But throughout this intricate tangle of interesting topics there was always a pattern growing, more visible to the author perhaps than to anybody else, but scarcely capable of definite explanation until the work had been discontinued. Our Chairman once reviewed a book published by the author at a stage when it was not safe to prophecy how the finished pattern would appear, and he made the sole objection to it that the "Cotton Plant" was not a subject upon which a book should legitimately be written. There is justice and some small revenge in his presence here to-day.

Those of us who have tried to develop the plant industries, realise, as few of us can realise, how small and struggling is the study of the living plant to-day, and yet how it will affect the civilisation of the states of the world tomorrow. Even the "man in the street" now realises faintly the totality of his ultimate dependence on plants for his food and his life, and there is hope that this realisation may serve to lift the science of botany from its preoccupation with dead things. To such leaders as Bateson and F. F. Blackman, who have organised clear thought in place of turbid speculation—the one for the plant, the other for its environment—that future will stand permanently indebted.

DISCUSSION.

The Chairman (Professor William Bateson) said that he hoped they would share the enthusiasm he himself had felt in listening to the paper. He said at the opening that science had scarcely been applied at all to tropical plants and sub-tropical plants, and when one considered the nature of these wide problems one realised how impossible it was to separate pure science and applied science. Let them think of the question of the water-table alone, which Dr. Balls had discussed. One might make graphs of the depth of water, the cotton produced, and suspect the relation of cause to effect, but to be really certain one must have considerable acquaintance with the physiology of plants. He shared with Dr. Balls the love of graphs. To show graphs of every stage in the formation of bolls was, he thought, an example of a new method of studying plants. They would see at once, when things were set out in that way, with what they were dealing. He hoped the study was one which would be very largely extended.

Professor J. A. Todd said that he had had the privilege of being associated with Dr. Balls in Egypt, and he thought that he had learnt enough about his work to know how little he (the speaker) really knew of the subject. His side of the matter was economic entirely. He was particularly interested in the machine which Dr. Balls had invented, because that had a definite economic bearing. The cotton crop had been falling off during the last year, and looked like sticking at a particular total when the Government decided to buy the Egyptian crop at a fixed price, and the result was that the "arrivals" at Alexandria had taken an unprecedented jump. The cotton was coming in because the price was fixed. He would like to add his personal appreciation of the work that Dr. Balls had done. It had been an extraordinary pleasure to see one of the results in the machine. It was as remarkable from a mechanical point of view as it was from a purely scientific.

Mr. C. F. Cross said they had listened to an entirely stimulating address on a subject of enormous importance which, through the *Journal*, would be made known to a wider circle than the present audience. Cotton was the basis of a large portion of our economic and industrial system. He hoped they would be able to impress on politicians and Government to see to it that, so far as depended on them, the lead we had in this country was maintained. It could only be done in one way; by accepting the whole gospel of science in the matter, and addressing themselves to the subject as intellectuals.

On the motion of the Chairman, a vote of thanks was accorded to Dr. Balls for his interesting paper, and the meeting terminated.

PROCEEDINGS OF THE SOCIETY.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 17th, 1918; J. AUGUSTUS VOELCKER, M.A., Ph.D., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Burley, Sydney Waterlow, Sittingbourne, Kent.
Kendrick, A. F., London.
Lawrey, William, Penzance.
Newman, James Harold, London.
Oliver, William Grant, London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Heine, William M., Connecticut, U.S.A.
Malcolm, George William, London.
Stobie, Victor, Gosforth, Northumberland.
Strachan, Robert Price, Bristol.
Weir, John Cunningham, London.

The paper read was—

AGRICULTURAL MACHINERY.

By FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England.

For many years before the outbreak of the present war, the agricultural industry suffered from a serious shortage of labour, and unfortunately the general publio took very little interest in the industry, partly from the fact that it is one carried on unostentatiously away from the great centres of population; moreover, so long as he can obtain the necessaries of life at a reasonable cost, the average man cares little whether they are produced at home, or, as has been the case with us in an increasing degree, imported—as to cereals up to four-fifths and as to meat to one-half of our requirements.

Agriculture, however, is the most important industry of this or any other country, and it should never be forgotten that it is one which requires as much skill and training as any of those other industries which figure more prominently in the public eye.

The crisis through which this country has passed during the last three and a half years, the realisation of the shortage of home food production, the peril of the submarine, and the indefiniteness of the duration of the war, have to a great extent dispelled this apathy and have awakened a keener interest about agricultural matters.

From the very important part which agriculture in this country has held—though scantily recognised either by Government or the general public, until present war exigencies forced it into prominence—it is but natural that with the advance made in industries generally, and in the processes connected with them, there should be a similar advance in the practice and use of implements connected with agriculture.

The state of efficiency to which such implements and machinery have attained might tempt one to a retrospect, to trace the origin of the machines and to follow their subsequent gradual development. Such a study, however, is quite beyond the scope of one paper. It is well known to all that such implements as the plough, or the methods of thrashing corn, are of the remotest antiquity, and it is evident from old carvings and illustrations that for centuries very little progress was made in their development. This fact is also substantiated by the crudeness of the methods and of the implements in use at the present day in some countries. During the last century and a half there has been a remarkable development, so much so that there is now hardly a process in agriculture to which mechanical science has not been applied.

When the Society of Arts was founded in 1754, it is recorded that "the implements then

available for the farmers' use were very few and of a very inferior sort." The plough and harrow were in use, but the hay and corn harvests were cut by hand with scythe and sickle, and the corn was thrashed by the flail. The Society at once directed its energies to the encouragement of agriculture, and for a long series of years, by means of awards and trials, successfully stimulated the development of agricultural implements, at the same time also furthering improved methods of agriculture generally; and this work it carried on regularly until 1838, when the Royal Agricultural Society of England was formed, and it became the representative society of British agriculture. It at once established a system of holding annual agricultural shows throughout the kingdom, where agriculturists and manufacturers had the opportunity of meeting and of exchanging opinions, and, following the example of the parent society, it offered awards and conducted trials of such new machines as presented themselves. These awards unquestionably gave a great stimulus to production and development of various implements. The agriculturist then had little or no experience with mechanical contrivances, and the award gave him a certain amount of confidence in the new implement and thus assured the manufacturer of a market. It must be remembered further, that at that time advertisement had not been raised to its present day "high art."

For the first few years after the foundation of the Royal Agricultural Society, trials of all new implements as they appeared were made each year. Later, however, when agricultural machinery had fairly established itself, and the agriculturist had recognised its advantage, conditions became materially altered, and it was found unnecessary and undesirable to have repeated competitions of the same class of machinery which might have become very unfair and harassing for the exhibitors, as well as misleading to prospective purchasers. It must be borne in mind that the manufacturer and the consumer do not always quite look eye to eye on the question of trials. The former may be over anxious to know the effect of any slight modification made in a machine, while the latter may very fairly resent having a competition—in which perhaps he has been successful—repeated because some other competitor may have made modification in his machine for which he claims great merit. Both arguments require, and have received, careful consideration.

Changes in the intervals of trials were made from time to time, and the system adopted of late years is, first, to decide what class of machinery is most in demand at the time by agriculturists, whether it be the improvement of existing machines or the introduction and development of new ones. Regulations are then drawn up, setting out the special features or improvements aimed at and the conditions under which the trials will be conducted. Such information is sent to the several manufacturers about twelve months before the trials, so as to enable them thoroughly to prepare and test their machines beforehand, and also enabling the engineering staff of the Society to make all necessary preparations for carrying out the trials and making them as thorough as possible. In practice this method has been found to work satisfactorily.

Agricultural implements have been conveniently classified into two groups:—

(*a*) Those for preparing the land for the crop and for sowing or planting the crop, which includes the various forms of ploughs, cultivators, rollers, seed drills, potato planters, etc.; (*b*) those for gaining the crop and preparing it either for market or for consumption on the farm, such as mowing and reaping machines, haymakers, thrashing machines with trussers and elevators, hay and straw presses, chaff cutters, grist mills, etc. This classification was complete so long as the several processes were carried out by horse-power. Now, however, we have to consider the question of prime movers in the various forms, whether steam or oil engines, water, wind, or electric power, in conjunction with the machine.

The Plough.

As no one can dispute the very ancient lineage of the plough, I shall not attempt to trace its early history. In 1773 Brand, a Suffolk blacksmith, is reported to have made the first plough, in which the frame was mainly of iron, and it would appear that even then great care was expended on the curve of the breast, so as to turn over a neat rectangular strip of soil, completely burying the growth on its upper surface. This resulted in the gradual lengthening of the breast.

As early as 1785 Robert Ransome, the founder of the well-known Ipswich firm, patented a process for tempering shares made of cast-iron, and in 1803 he took out a patent for "chilling" the under side of cast-iron shares, which previously rapidly became blunt with wear. In 1852 Mr. James Howard patented the chilling

of the breast of the plough. These two developments constitute certainly the most important phases in the construction of the plough.

The application of a wheel or pair of wheels to reduce the work on the man working the plough, as well as to reduce its draught, was first shown in this country in connection with an iron-framed plough at the Royal Agricultural Society by Mr. John Howard. The principle, however, was not new.

The double-furrow plough—though apparently used in a crude form in the time of the Commonwealth—was developed about 1802 by Lord Sommerville, who took out a patent for it, and did much towards its introduction. It was subsequently much improved upon by Mr. Thomas Pirrie (1867), who introduced a friction wheel behind the plough in the angle of the furrow, in place of the slade, to reduce the draught. A three-furrow plough was invented by the Rev. Dr. Cartwright, for which he received a medal from this Society, in the description of which he pertinently describes the advantage to be obtained by a multiple plough, thus: "In a single plough a certain length and width are required in those parts of it to make it go steady . . . when two, three, or more ploughs are combined, they serve to steady each other." The friction on the land side of the plough is also materially diminished. For some few years the double-furrow plough was fairly used, but it fell into disuse for some reason or other until the last twenty or twenty-five years.

The types of ploughs with their varying forms of shares and breasts are now numberless, and it is difficult to get any general agreement as to the merits of each, so much has old custom and use to do with the selection of any one type, as evidenced by the differing types used in the several counties. With the view of obtaining a uniform unbroken furrow, and also of reducing the draught, the length of breast was increased with a more gradual incline. Now, however, the tendency is to shorten the body of the plough and make the breasts approximate more to the digging breasts.

On the question of comparative draught, I can but quote in brief my remarks in the report of ploughing trials at Warwick by the Royal Agricultural Society in 1892, "unless you have precisely similar conditions of the trials and soil, both as regards the nature of the soil and its moisture, comparisons may be very misleading."

The diagram on the screen shows what difference of draught there may be between two fields on one farm. The mean draught in one case with a three-furrow plough being 7 cwt. on the draw bar, and in the other case 44 cwt., with similar plough.

The area which might be ploughed with a single-furrow plough must be controlled by the rate at which a man can walk behind it throughout the day. This is found not to exceed two miles per hour, which with a furrow 10 in. wide, and allowing a slight margin for turning at the ends of the furrow, gives 1·3 acres in eight hours. Anything which accelerates this rate of work is of the greatest advantage, it being of the very first importance to get the ploughing done in suitable weather. The farmer, therefore, was ready to welcome the application of the steam engine to expedite the work.

As early as 1866–67 an inquiry was made by the Royal Agricultural Society on the subject of steam cultivation, and a most interesting report gives details of the work done and comparative costs of it for the period 1858 to 1865, the average amount of work done being at the rate of six acres per diem. Direct haulage of the plough by the engine was tried as early as 1865, but objection was taken to the weight of the engine, traversing and compressing the land, and this method was for the time abandoned.

In 1870 the Royal Agricultural Society arranged for a competition of steam ploughing-plant to be held in connection with its Wolverhampton show in 1871. There was a large number of competitors, and the several systems then in vogue were duly represented. The results of these trials were of a most conclusive nature, and are fully reported in Vol. VII. (1871) of the Society's *Journal*. The adaptability of mechanical haulage to ploughing was conclusively demonstrated, and of the several systems, such as: (*a*) The double-engine system, with an engine at opposite sides of the field hauling the plough backwards and forwards between them by means of a wire rope; (*b*) the single-winding engine with travelling (Campain's) anchor on opposite headland; (*c*) the roundabout system, in which a portable engine drove direct by means of a "Hooks" coupling rod, a double windlass, the ropes from which were guided by grooved pulleys at the corner of the space to be ploughed; (*d*) the high-speed roundabout rope system of Mr. Fisken.

The double-engine system proved its pre-eminence for getting through the work efficiently in any case where the fields are of moderate or large size.

The travelling anchor system was not so

satisfactory. Difficulties and delays arise with the travelling anchor, which would be emphasised were the ground soft.

The roundabout system, I remember, appealed to many, as being specially applicable to small holdings where the farmer was already in possession of a portable engine. It, however, entailed a very undue amount of attendance, especially in setting to work.

The comment of the owner of one of such sets, who wanted to replace it by a double engine set, to the effect that "it did its work well, but remains too long in one field," precisely summarises the position.

The high-speed rope tackle was an interesting application to ploughing of the high-speed rope drive as used for working travelling cranes in engineering works. It consisted of an ordinary portable engine having a groove turned in the fly-wheel to carry the driving rope, which encircled the field, and communicated motion to the hauling gear of the plough. One great claim of the inventor was that the engine need not be taken into the field, but may be placed in any neighbouring position close to a water-supply and convenient for delivery of coal. Such advantage was more than outweighed by the very excessive attendance and wear and tear involved, in addition to which there was frequent trouble with the slackening and tightening of the rope with any change of weather.

Of all the systems the one which has maintained its position is the double-engine system, which, for efficiently getting through a large amount of work is still pre-eminent. I am enabled to state on the authority of one of the leading steam-plough makers that of approximately 540 sets of double engines sets (similar to those tried at Wolverhampton) at work in this country, 267 are over forty years old, 99 between thirty and forty years old, 13 between twenty and thirty years old, 28 between ten and twenty years old, and 133 under ten years old.

With the advent of the oil tractor a new condition was created, and in 1897, at Manchester, prizes were offered for the best agricultural tractor. Only one, however, presented itself, and it failed to complete its trial. The following year, 1898, at Birmingham, prizes were offered of £100 and £50 for vehicles to carry up to one ton and similar prizes for vehicles to carry three tons. In the result, only one prize in each class was awarded.

The diminished weight of the oil tractor led to a material modification of former views with regard to the direct haulage of a plough or cultivator. Consequently the Society offered prizes for a competition in 1910 of the best agricultural tractor (steam or oil) suitable for direct haulage of cultivating or harvesting machinery, and to be also suitable for road traction or driving a thrashing machine or other farm machinery. Seven machines were entered —three steam engines and four oil tractors. In the result the best and most economical work was done by the steam tractor. The oil tractors, however, showed clearly that with further development they would give very different results. Their design and also workmanship were crude, and from want of experience the competitors expected too much of them, and gave them too heavy a task to perform. In these trials the weights of the several motors varied from two tons to six tons, and they were all tried on similar plots of five acres in the same field, and it is interesting to note that no appreciable difference could be distinguished in the succeeding crop, and, as further evidence that no harm was done, I may say that the farmer has now had two motor tractors at work on his farm for some time, and has a motor plough on order, in addition to them. I have not been able to collect any such positive evidence in the opposite direction as to the injury done by a given weight travelling over the ground in compressing the soil. Since the date of these trials the development of the motor tractor has surpassed that of any other agricultural machine, whether it be in its variety of designs or the number of manufacturers in this country and America who have taken it up.

A most interesting and instructive paper, entitled "Traction on Bad Roads or Land," was read in January last by Mr. Legros before the Institution of Mechanical Engineers, and published in the Institution *Proceedings*, which gives a very careful and comprehensive description of motor tractors, and to which I would refer any one wishing to inquire further in the matter.

Previous to the outbreak of the war, the Royal Agricultural Society had decided to hold further trials of agricultural tractors in 1915, the conditions and regulations having been published and circularised in July 1914. Unfortunately the war necessitated their postponement. In the meantime, however, much valuable experience is being gained at the war front, where the caterpillar system of the tanks has

accomplished so much success and attracted so much attention, and has been taken up by several of the leading manufacturers, as well as in the use of the several types of tractors in this country ploughing up the additional area of land required. It will be then for the manufacturers to evolve a general utility machine for agricultural purposes, which will of necessity vary somewhat from what may have proved itself best for either of the above purposes. The proposed trials for 1915 have only been postponed, and it is the intention of the Society, so soon as a normal condition is resumed, and the manufacturers have had time to make the necessary preparations, that they shall take place. After careful consideration, prizes were offered for four classes, viz. :—

Class I.—Direct internal-combustion plant of 20 b.h.p., to plough not more than four furrows, 9 in. wide by 6 in. deep.

Class II.—Direct internal-combustion plant over 20 b.h.p., or steam ploughing outfit suitable for ploughing not more than six furrows, 10 in. wide by 8 in. deep.

Class III.—Self-propelled plough turning not more than four furrows, 9 in. wide by 6 in. deep.

Class IV.—Plough suitable for direct tractor work, turning not more than six furrows.

1. For the purpose of such trials an "agricultural tractor" shall be capable of: (*a*) Hauling direct in work, a plough, cultivator, harvester, or other agricultural implement; (*b*) driving barn machinery; (*c*) hauling a load along a road and on the land.

2. The machines shall be tested for efficiency in carrying out all classes of work. The following are some of the points to which special attention is directed: (*a*) Weight of machine; (*b*) weight per inch width of wheel; (*c*) mechanical design and construction; (*d*) adaptability to various kinds of work, such as harvesting and the like; (*e*) ease and safety of handling; (*f*) ease of turning and space required for same; (*g*) efficiency of winding gear; (*h*) facility of attachment; (*i*) attendance necessary; (*j*) consumption of fuel, water, and other supplies per unit of work done; (*k*) price.

Bearing on these, I might mention, under the heading of "Ease of Turning," that most motor tractors with a plough behind them do leave an unduly wide headland, and that the frequent passage of the motor along the headland each time it turns may unduly compress the soil, making it desirable that the plough and tractor should be as compact as possible. I know that this question was certainly recognised by some manufacturers who were working in the direction of getting over the difficulty until stopped by the exigencies of the war.

With the motor plough, in which the motor and plough form one combined machine, the width of headland is materially reduced, but there is a considerable loss of time in turning at the end of each series of furrows. From actual observation in ordinary work the mean time occupied in turning on the headland and getting into work cannot be put at less than one minute, and taking a field 500 yards wide, with the plough travelling at the rate of 3½ miles per hour, the time lost amounts to 20½ per cent. of the total time, increasing with a lessened length of furrow. This loss might be materially lessened by the adoption of a balanced plough, similar to that used with the double-engine steam sets. The cost of the motor and the plough would of necessity be increased, but the saving in time might well repay the extra outlay.

Work done: The speed at which it is desirable for the plough to travel requires definite consideration; whether it is better to travel at a high rate of speed with a two or three-furrow plough, or at a slower rate with a three or four-furrow plough. The motor, provided it is of sufficient power, will meet either case, but existing patterns of ploughs designed for a slow speed will not hold in the ground at a high speed, especially if they are working on a gravelly or stony bottom.

Attendance necessary is an exceedingly important point; it is most desirable with the inevitable shortage of labour to reduce the number of attendants to a minimum. Price is also a consideration, especially in the case of moderate-sized farms. There are other vexed questions, such as: Whether the tractor should have three or four wheels, and whether the driving wheels should run on the land side or in the furrow. If the latter course is to be adopted, the width of furrows must be increased to accommodate the width of the wheel. There is still a lack of uniformity in the diameter and width of wheels. Anything in the direction of approved simplification and standardisation is most desirable, and would prove of great advantage both to the manufacturer and the user.

Under the term of cultivator, I would include scarifiers and grubbers, one of which, Finlayson's grubber, patented in 1844, consisted of a frame carrying curved prongs mounted on three

wheels, the foremost running on a curved axle by which the frame may be raised or lowered on the wheel so as to put the prongs in and out of work. In this machine you have embodied the main design of the modern cultivator, which may be divided into three classes: (*a*) Rigid tine cultivators; (*b*) spring tine cultivators; (*c*) disc cultivators.

The cultivator generally follows the plough, though in some cases it is used for breaking up the land, especially when it is very hard, for which the rigid tine cultivator is used. Intermediate between the rigid tine and the spring tine cultivator is an implement which does very good work, in which the tines shaped like rigid tines are mounted on the frame through a steel spring connection. This gives a certain amount of play to the tine, and in the event of coming into very stiff land the tine comes up against a stop and acts as a rigid tine. The spring tine cultivator, introduced in the first instance from America, does good work after the ground has been broken by the plough, and prepares an excellent seed-bed. The disc cultivator consists of a series of steel discs mounted somewhat obliquely to the travel of the machine. The discs cut up the rough soil and rapidly reduce it to a fine bed. In its lighter forms it is used as a disc harrow. When these implements have to be used with a motor plough, they are so mounted on a frame as to be interchangeable with the plough, which would be removed from the motor.

Before leaving the implements for breaking up the land, I may call attention to some of the efforts made in mechanical digging. One of the first substitutes for a plough was a revolving cylinder with radial prongs or tines (1846), and by making the speed at which these revolved independent of the rate of travel of the machine, the ground was to a certain extent broken, and such a machine was reported in 1855 to do "its work most perfectly, leaving the land sufficiently pulverised to be quite ready to receive the seed." In hard ground, however, the tines of some of these rotary diggers revolving in the same direction as the travel of the machine, would not enter the ground. To get over this, in 1857 a machine was patented with the revolution of the tines in the opposite direction to that of progress; the tines having once opened a way enter the ground on the already broken surface. This action, however, caused the earth raised to be thrown over the axle of the tines, and could not be considered satisfactory.

At Carlisle, in the year 1880, Mr. Darby first exhibited his digger, where it was tried, and, though the ground was wet and very hilly, certainly did successful work, proving the practicability of mechanical digging. Its weight, however, was 15½ tons, which was excessive, and it was considered that the earth was not sufficiently broken up after having been submitted to so much compression. The accompanying slide conveys an idea of the plant. The next development of this system of digger was its adaptation to the rear of a traction engine, the digging forks being driven at a much higher speed than in the original Darby digger. This machine was tried at Leicester in 1896, and again at York in 1900, when prizes were offered for a competition of steam diggers. The work done was excellent, and the machine received an award on each occasion.

Other more recent diggers have not proved satisfactory, nor has the system of steam digging been taken up by the agriculturist.

Harrows.

The first idea of this was the primitive Bush harrow, which still does good work on grass land, and has developed into numerous types. The zigzag harrow with its rigid tines originated about 1839, and chain harrows—to take the place of Bush harrows—emanated from Smith of Doncaster about 1842.

Rollers.

It is unnecessary to comment much on these. The division of the wooden cylindrical roller into two lengths very materially facilitated its turning. The Cambridge roller, or ring roller, patented in 1841 by Crosshill, is of its class a most efficient machine. The manner in which the several rings are mounted on the main axle, allowing for a certain amount of play between them, enables the roller to adapt itself to irregularities of the surface and also prevents the soil clogging on the face of the rolls.

Seed Drills.

Next in order of machines comes seed drills, the special features of which are: (*a*) The precise regulation of the quantity sown per acre of any given seed; (*b*) the efficient planting and covering of the seed, regulated by the depth and angle of the coulter at the end of the delivery tube; (*c*) facility of steerage so that each bout of a machine may be kept actually parallel and equally spaced.

One of the earliest forms is the cup drill, which on fairly even ground gives a wonderfully

uniform delivery, and has done excellent work in all competitions. It is very generally adopted throughout Europe. Another form of drill consists of a long seed box, more or less triangular in section, with several holes pierced in the bottom leading to the delivery tubes, the delivery of the seed through these holes being regulated by either a revolving pinion or brush or by a revolving disc with an irregular flange, the recess in which would allow the seed to pass, while the projections close the apertures.

Potato Planters.

In connection with seed drills must be included the potato planter, which may be arranged for planting either one or two rows. The accompanying slide shows a single-row machine, consisting of a hopper mounted on travelling wheels, in which the tubers are placed. An endless chain fitted with small dredger-cups picks up the tubers from the hopper and delivers them down the delivery tube into the furrow.

Although out of order, I may here refer to the potato digger. The first machines of the kind consisted of a wide-shared plough with double flexible breast, formed of wrought-iron rods free to some extent to move. The share passed well under the tubers, the earth raised with the potatoes was sieved through the open breast and the tubers were delivered to each side. This did not collect the potatoes in a sufficiently limited area for collecting. The most approved form of machine now consists of a plough—as before—with a revolving wheel at the rear, with feathering tines or forks arranged round same. These separate the potatoes and deliver them gently in one row alongside the furrow. As a labour-saving machine it is most efficient.

Manure Distributors.

An equable distribution of manure over the land, both from the point of economy and of efficiency, is most important. For the distribution of farmyard manure, such distributors consist of a waggon with a travelling false bottom actuated by gearing from the travelling wheels of the waggon. Across the rear end of the cart is a spindle or drum with a series of pins fixed therein; this, actuated from the driving wheels of the cart, combs out the manure as it is fed up to it by the action of the travelling false bottom. So long as the manure is short and well rotted they work admirably, and I have met users of them, who, taking care that they should work under such conditions, have been fully satisfied with them, but if they have to deal with anything in the way of longish straw they choke hopelessly. There is, further, the drawback of the waste of time in supplying them with manure, and it is quite an open question whether—provided there is a sufficiency of labour to distribute the manure by manual labour—a greater acreage per day cannot be effected without the aid of a distributor. We have now to deal with a serious shortage of labour, and without saying that the implement as it stands to-day is not capable of material improvement, I say it behoves the agriculturist to see that suitable manure is put into the machine, as I do not believe that any machine will deal with unsuitable material. A really efficient distributor for farmyard manure is yet to be devised.

Artificial manure distributors either distribute the manure from a long box—corresponding very much to the box of a seed drill—from which it is distributed close to the ground by revolving stirrers which give a very uniform distribution; or else by means of centrifugal distribution in which the manure is placed in a hopper with an adjustable graduated opening at the bottom, by which the quantity per acre may be fixed, and it is then delivered on to a disc revolving as high speed with radial—or otherwise—projections thereon, which scatter the manure broadcast. To ensure an adequate trajectory these distributing discs must be a certain height above the ground, and if any wind happens to be blowing it must affect the distribution of the manure, and it is also inevitable that the larger particles carry further than the smaller ones. They are however, very compact simple machines, easy to manipulate, and if worked under suitable conditions give efficient results.

Reaping Machines.

Passing now to the second class of machines, those for gaining the crops, mowing and reaping machines occupy the first place, and I shall take the development of the reaping machine to apply to both.

The efforts made to supplant the scythe and sickle date from the time of the Gauls, but the progress made was insignificant. In 1780 this Society offered a gold medal for a reaping machine, and renewed the offer for more than twenty years without practical result. In the year 1806 a Mr. Gladstone invented a very remarkable machine embodying many of the leading features of the machine of to-day, such as: (1) the horse walks alongside the upstanding corn and well clear of it; (2) the action of the

machine tends to deliver the cut grain away from the standing corn, leaving a clear way for the horse on the next bout; (3) the mechanism is arranged between the two driving wheels.

Omitting intermediate machines, Common, a millwright in Northumberland, was the first to respond in a practical way to the offer made by the Society of Arts in 1812, in which he used open finger bars with reciprocating knives, a reel for holding the grain to the cutters, and a swathe delivery. Popular prejudice appears to have been against a reaping machine, and he did not proceed further.

The next important development I shall notice was made by the Rev. Patrick Bell, who placed his machine on the market in 1826. The cutting was done by open pivoted shears. The machine was pushed, and it had a revolving reel above the shears and an inclined apron behind them. This machine, with the addition of Hussey's open -guard cutting apparatus, was exhibited in the 1851 Exhibition, and it formed the rock foundation upon which further developments were built. From this time the progress of invention has been more rapid in America than here.

However interesting it might be to follow the further growth of the reaping machine in either country from the time when the division of the sheaf was done by a man walking by the side of the machine, then being carried thereon until the growth of the self-binder, time will not permit. I therefore pass to the trials of self-binder reapers in this country.

The first binder was exhibited by Messrs. Walter A. Wood in 1876 at Birmingham, but not being attached to a reaper it was impossible to try it. At Liverpool in 1877 a gold medal was offered for the best self-binding harvester, and three binders using wire and two using string competed. None worked sufficiently well to justify an award. Further awards were offered the following year at Bristol (1878), when three wire binders and one string binder competed. The award went to the wire binder, which did its work successfully.

Serious objection being taken to the employment of wire in binding straw which might be used as fodder, the Royal Agricultural Society offered a gold medal for a competition of binders in 1881 at Derby, using material other than wire. There were seven machines competing, and the gold medal was awarded to Messrs. McCormack. Further trials were conducted at Shrewsbury in 1884 with string binders, the awards going to Messrs. Hornsby and Messrs. Howard. The latest trials took place in 1893 at Chester, when the work done was almost as perfect as could be wished, the details of the Appleby knotter had been thoroughly mastered, and the percentage of imperfectly tied sheaves was quite insignificant. The separation of the sheaves was satisfactory. The uniformity of weight gave evidence of the efficiency of the packing, and the butting appliances satisfactorily regulated the position of the band.

During the time which has elapsed since the date of these trials, further improvements have been carried out, and though there was but small margin for improvement in actual work done, there has doubtless been considerable gain in the simplification and reduction of the number of parts, of improvement in the driving gear, in the introduction of roller and ball bearings, and last, but not least, of the height to which the grain has to be raised before binding. All these features tend to improve working of the machine and to a reduction in the draught. Attempts have been made to have a combined engine or motor and reaper; in 1876, at Birmingham, Messrs. Aveling exhibited a traction engine working a reaper with a 12 ft. cutting width, for which they were awarded a gold medal.

At the Paris Exhibition, 1900, Messrs. Deering and Messrs. McCormack both exhibited a reaper with combined motor, but nothing further seems to have come of the combined machine. At present preference is given to the hauling of one or more reapers by an independent tractor, as shown.

It has been suggested that a desirable development of the reaping machine should take the form of a combined reaper and thrasher, and attempts have been made in that direction. Necessarily this means a heavy cumbersome machine; there are, however, difficulties about its application to harvesting in this country: (1) Absolute uniformity in the ripeners of a crop in any field cannot be assured. As ripening continues after corn is cut, this matters little when the corn is allowed to remain in the sheaf. To thrash it immediately would bruise the unripened grain; (2) where clover or seeds are growing with the corn, it would inevitably choke the machine. The same would occur after a shower of rain, and operations would have to cease until the straw was dry enough to pass through the machine; (3) on ridge and furrow land, which is so common, the inclinations and levels of riddles, screens, etc., would be

continually varying, and efficient separation would be upset.

Haymaking.

The mowing machine being but a simplification of the reaping machine, I need here only state that for small-holdings a separate reaping attachment is made which converts the mowing machine into a reaper.

The early forms of haymakers consisted of a revolving skeleton cylinder with prongs mounted thereon, which by means of gearing revolved in the opposite direction to that of the travel of the machine, the hay was thus thrown over the machine, and though thoroughly loosened, was considerably knocked about. Subsequently the direction of rotation was reversed, making it the same as that of the machine, but running at considerably higher speed, the result being that instead of tossing the hay over the machine it was just lifted lightly off the ground and shaken out. This in a modified form is a useful machine where dealing with ridge and furrow. To reduce the bruising of the hay, several forms have been introduced, such as the hay tedder or kicker, which consisted of four or more spring forks mounted at the rear of the machine and actuated by levers and cranks which gave the forks a motion approximating to that of a hand fork, and gently turned the hay. The swathe turner was introduced with the same object in view. At first it consisted of two sets of screw blades, mounted on longitudinal shafts, at the rear of the machine, spaced to coincide with the spacing of the swathes. The blades had a serrated or saw edge, which in revolving just turned the swathe gently over. The latest arrangement consists of two or more spring tine rakes, the full width of the machine, placed at a slight angle to the machine and actuated in such a manner as to have a combined vertical and horizontal motion, independent of that resulting from the travel of the machine. The rakes may be so set that with one machine the several operations of tedding, swathe turning, and wind-rowing may be accomplished.

For collecting and loading hay several special rakes and loaders have been from time to time used in different parts of the country. At the present time any machine which will effectually take the place of hand labour is in demand, and we shall doubtless see loaders similar to the larger rick elevators in miniature placed behind the waggon in much more general use in the immediate future.

The most usual form of rick elevator is that commonly attached to the thrashing machine, consisting of an inclined Jacob's ladder, actuated either from one of the motions of the thrasher or else by independent horse-gear. Another form of elevator consists of a mast or pole with a lifting boom with pullies, through which a rope is reeved with a large fork suspended therefrom. A horse at the other end of the rope pulls up the fork with its load. Such an elevator was in constant work for several years about 1855: with it, however, the hay or corn as it was loaded into the cart was bound by two ropes, and was then lifted bodily out of the cart on to the rick. The work was done most expeditiously.

Thrashing Machines.

Without tracing the development of these from the thrashing floor of Araunah, or even much earlier, there are I presume some here who have seen the hand-flail in use as the means of thrashing, in which there was very little departure from the earliest methods. The first attempt at mechanical thrashing took the direction of working flails mechanically. Such was the nature of the machine invented by Mr. Menzies of Dalkeith in 1772, and of which it is stated that it "in a minute it gives 1,320 strokes, as many as thirty-three men thrashing briskly, and that it does not take more room than two men." It is not surprising that the machine knocked itself to pieces. The next development also emanated from Scotland, invented by Mr. Michael of Dunblane about 1750, on the principle of a flax-dressing mill worked by a waterwheel. We next find rollers applied for squeezing out the grain, as in the case in Rastrick's machine (erected 1778) in which rollers are combined with beaters.

The drum of to-day combines both the rubbing and beating actions, and has necessitated the expenditure of considerable thought and experiment to ensure efficient separation without injuring the grain or damaging its germinating properties. Such early machines as these were fixed in the barn building and were driven either by water-power, horse-power or a fixed steam engine, some of which were of a most primitive type. It was only about the middle of the last century that the movable thrashing machine and portable engine came into vogue.

Of the various farm implements perhaps none has gone through so many alterations and additions: the machines now have multiple blast, improved riddles and shakers, and leave but little to be desired in the samples of corn they turn out. Certainly they are the greatest

labour-saving machine on the farm. They are made from 3 ft. length of drum up to 6 ft. The larger machines go exclusively to the foreign markets. The most usual size for this country is the 4 ft. 6 in. machine, which deals with about seventy bushels of wheat per hour, and takes 16 b.h.p. to drive it. There is an increasing demand for the smaller machines consequent on the use of low-powered tractors, and also because the smaller farmers are now requiring machines.

Straw Elevator.

In conjunction with the thrashing machine a straw elevator is commonly used, where the straw has to be stacked. The first of these was exhibited in 1847, since which time many improvements have been made in arrangements for raising and lowering.

Straw Trusser.

In 1883 Messrs. Howard adapted the principle of the sheaf-binder to the packing and tying of the straw as it drops from the shakers. When the straw is to be immediately marketed this is a most important adjunct to the thrasher.

Straw Presses.

Owing to the bulky nature of straw or hay, presses of various designs have been devised for compressing it into bales. The Pilter Press was one of the earliest, consisting of a revolving cylinder into which the hay or straw is fed by means of two conical rollers, which twist it into a rough band, the amount of compression being regulated by the pressure on a plate closing the back of the machine. The density varies from 12 to 25 lb. per cubic foot. There is also the continuous press of Messrs. Howard, in which the hay or straw is delivered and packed into a long rectangular trough having a plunger with reciprocating motion, and when the desired compression is obtained the bale is wired and passed out of the machines. Hand baling presses are largely used for baling from the rick. Trials of these were conducted at Nottingham in 1888. For general purposes it does not seem necessary to resort to excessive pressures; so long as a ton measurement can be made to weigh a ton most requirements will be met and the straw will not be so severely broken up.

Chaff Cutters.

I now come to the several machines used in the farmstead for the preparation of fodder, etc. First of these is the hay or chaff cutter, the design of which has settled down to that of the revolving radial knife introduced by Comes in 1547, although there were earlier forms. The form and number of knives has been varied, but the convex form is now usually adopted. The features to which special attention has been devoted are the feed arrangements, safety appliances and guards in power-driven machines, in order to comply with the "Chaff Cutting" Machines (Accident) Act 1887.

Grist Mills.

It is difficult to put a date to the introduction of grist mills as such, as the regular preparation by grinding of food for cattle is of relatively modern growth, and the existing millstone was used for such purpose. They may, however, now be divided into: (1) Millstones; (2) flat metal discs serrated; (3) conoidal discs; (4) grooved rollers and breast; (5) rollers. These various machines were tested in competitive trials at Plymouth in 1890, and for general purposes the flat metal discs were proved to give the best results. There are also several forms of root slicers and pulpers. Such machines are ordinarily arranged in a food-preparing building and driven by an independent fixed engine. The power required being small it is not desirable to use an engine of such power as is necessary for ploughing or thrashing; it is found much better to have a small fixed engine of some 5 or 6 h.p. At present an oil engine is most suitable for the purpose, but where electric power is available nothing is more suitable than a small electric motor driving a line of shafting, the several machines being driven therefrom by fast and loose pulleys.

Prime Movers.

I shall now refer briefly to prime movers, which might well form the subject of a separate paper. Wind power was utilised at an early period, but owing to its uncertainty and irregularity it cannot be counted upon now for the carrying out of any work which should be done at a specified time and at a regular speed. Water power was used for driving many of the early fixed thrashing machines. There are many places where small water powers are available which have not been utilised. In any such cases advantage should be taken of them to drive an electric plant, from which not only may the lighting of the farm buildings be effected, but power for driving the farm machinery may be obtained. I can cite instances where disused water power flour-mills have advantageously been adapted to this

purpose. The portable steam engine has of late years been the most universally used. In its earliest form it consisted of a vertical steam boiler and independent vertical engine fixed on a platform mounted on low wheels. In 1842 there is the account of a high-speed disc engine which was successfully used to drive a thrashing machine. The same machine was exhibited a year later, the platforms carrying it having been enlarged sufficiently to take a thrashing machine, and the engine was self-propelling, so that the plant might move from farm to farm.

In 1849 the Royal Agricultural Society held its first trial of portable engines, built somewhat on present lines, *i.e.* with locomotive-type boiler and horizontal engine fixed thereon.

Time will not permit to go into the progressive improvements made. The diagram on the screen, plotted from the results obtained at various trials, however, gives a record of the advances made: (*a*) In 1849, when the engine was in its infancy, prizes were awarded to Messrs. Garrett and to Messrs. Clayton and Shuttleworth for their engines, the coal consumption then being 11·5 lb. per b.h.p.; (*b*) the next trials were held in 1850, when with a steam pressure of 45 lb. the consumption was reduced to 7·5 lb. per b.h.p.; (*c*) further trials were held in 1872 at Cardiff, the engines working at 80 lb. per sq. inch, the consumption was 2·75 lb. per b.h.p. These trials were most remarkable, as in the first trial two engines ran practically a dead heat and a second trial was made; (*d*) in subsequent trials at Newcastle in 1887, when the consumption was still further reduced to 1·85 lb. per b.h.p.

Looking at these results it may be pointed out that the great gain in efficiency between the first and second series of trials was due to improvements in design and increased steam pressure; and that between the second and third the gain was due to similar causes, but as might be expected at a very greatly reduced rate. When, however, we come to the Newcastle trials, following the dotted line of the diagram, which gives the results for the single engine—we find but very slight improvement, showing that for this type of engine as it stands finality is approached. And, following the red full line of the diagram, a largely increased improvement is due to the introduction during the interval between the trials of the high and low press cylinders or compound engine with its expansion valves. These last results were eminently satisfactory, as, considering the power of the engine, they compare favourably with the best results obtained by large power pumping and marine engines of the same date, which had the advantage of working as condensing engines. The temperature of the waste gases in the smoke box was reduced to a minimum. It remains to be seen what further economy may be effected by the use of superheated steam, which is now being applied in some engines.

Traction Engine.

The traction engine on the farm one is inclined to associate with the early endeavours made in road locomotion, though I have come to the conclusion that this is incorrect. During the period from 1825 to 1835 steam carriages were successfully carrying passengers from Paddington to the Bank, charging sixpenny fares, as well as in other parts of the country. That such was being done with a certain amount of success is beyond question, as a committee appointed by the House of Commons in 1831, and reporting in 1832, stated in brief: That carriages can be propelled by steam on common roads at an average rate of ten miles per hour, conveying upwards of fourteen passengers That they are perfectly safe for passengers. That they need not be nuisances to the public. That they are speedier and cheaper than horse-drawn carriages. That they admit of greater breadth of tyre than other carriages, and roads are not acted on so injuriously. That rates of toll have been imposed on steam carriages, which would prohibit their being used on several lines of road were such charges permitted to remain unaltered.

The last opinion expressed by the committee would appear to have been only too literally fulfilled, and the industry appears to have completely disappeared, and, indeed, history repeating itself, we all know how in later years the motor-car industry—to which we owe so much for the development of automatic machines, jigs and the like in engineering works—was for years driven out of this country to the Continent.

The agricultural traction engine has developed from the portable engine. I find as recently as 1859 a patent taken out by Mr. Aveling, of Aveling and Porter, which I think pretty conclusive on this point. I show it as a lantern-slide, from which it will be seen that a small sprocket wheel has been fixed on the crankshaft of a portable engine, which drives by means of a chain on to a larger sprocket wheel attached to one of the main road wheels of the engine. Later the shafts of the engine were substituted by a triangular iron frame with a fifth wheel pivoted at its apex, the steering being done through a tiller arm by a steersman seated in front of the

smoke-box. The chain drive in this engine continued in use until about 1872, when steel-cut gearing was substituted. Subsequent developments consisted in worm wheel and chain steerage from the platform of the engine, compound cylinders in 1880, spring mounting of the wheels, etc., in 1894. The design and workmanship of these engines by the leading makers leaves little to be desired.

Of late years there has been the introduction of the motor tractor and waggon. The former I have already referred to, the latter is a most convenient vehicle, as it dispenses with all the waste time in getting up steam on intermittent work, and is very easily handled.

It is to be hoped that with the experiences gained both at the seat of war, and with the effort being made by Government towards increasing the tillage area of this country, the advantages of motor transport will be realised, and that there may be some amelioration in the restrictions now controlling their use.

Water-supply.

There just remains one subject, and that an important one, to which I should refer—namely, the means of supplying water to the farm. Here the conditions vary very considerably.

If a moderate fall is available from a spring yielding good water, no more efficient method can be adopted—for a moderate supply—than that of a hydraulic ram, with a good storage tank at sufficient elevation to command all buildings. On the other hand, if the water has to be pumped it may be done, if the locality is favourable, with a wind engine, provided that sufficient storage is provided to carry through the longest period when there is little or no wind. In some cases the cost of this is excessive. An oil engine and pump is at present found generally the most convenient.

If water power is available, a small water-wheel or turbine with its pump may be used, but if such power is sufficient it is better, as I have already suggested, to utilise it in generating electricity and work the pump by means of a small motor. Electricity lends itself so easily to facile distribution that where possible it should be used.

I do not touch upon dairy machinery; this may well be dealt with separately. The success of the different appliances is so closely associated with the processes with which they are connected that they may be better dealt with in connection with them, rather than merely technically.

I have incidentally referred to the application of electricity for working farm machinery, but I believe there will be a very great move in this direction before long. Only a short time ago a very interesting paper was read here by Mr. Newlands on his work in connection with the investigation of water powers in Great Britain by a commission appointed for that purpose, and of which he is a member. True, the powers available as compared with those of other countries are but small, but for the most part they are in rural districts, and the very first persons who ought to avail themselves of such power are the agriculturists in their neighbourhood who may be in need of power. Much more important than this, however, is the work being done by another commission dealing with the conservation of our coal consumption; and there is every reason to hope that in the near future we shall have large generating stations close to the collieries, which will distribute high-tension current over extensive areas—as is done at Niagara and other places —which will open up a vista, the full extent of which at present it may be difficult to realise. But, given such distribution of power, at a price which will compete favourably with existing power, I have no doubt but that it will be readily adopted, as its convenience and adaptability will commend it for the several purposes required by the agriculturist. It has already been used in more than an experimental manner for ploughing, etc.

It may be asked even of such implements as I have referred to in this paper, how the smaller farmer, who is not a capitalist, is to equip himself with the needful machines.

I am quite sure with the inevitable shortage of labour, if the agriculturist is to keep pace with his foreign competitors, there will be the necessity for a considerable increase in the use of machinery, and I believe at the present moment he cannot do better than consider and evolve a system of co-operation in his district or county, and not only that, but each area—of heavy or light land—should decide precisely what type of machine is best suited to its requirements: in this I know he will receive the cordial co-operation of manufacturers, as it will tend to diminish the number of special machines, many of them of little use, which have been designed by or for "faddists," and it will further tend to simplify and standardise those of proved merit.

Where in the course of this paper I have referred to the names of certain makers, I have

done so merely because their name has been associated with a certain machine at a certain date. Where so many truly excel, it would be invidious to make any attempt at differentiating among them.

[The discussion on this paper will be published in the next number of the *Journal.*]

THE BUTTON INDUSTRY OF TONKIN.

The button factory at Hanoi is owned and operated by La Compagnie Industrielle du Tonkin, a joint-stock company with a capital of 350,000 francs (£14,000). The buttons are made of mother-of-pearl, obtained from the shell of a small mollusc (*Unio affinis*, Lea) found in abundance in nearly all the rivers of Tonkin and northern Annam, especially the Song-Ma near Thanh-hoa (Annam) and the Song-Cau near Bacninh (Tonkin). For years this mother-of-pearl has been used by the native artisans of Bacninh for inlay in furniture and other wooden articles, but the Hanoi button factory represents the first attempt by Europeans to exploit this resource.

According to a report by the United States Consul at Saigon, the factory consumes about 400 tons of shell a year. Last year it produced about 14,000 gross of buttons per month, but the monthly production will probably be raised to 20,000 gross within a year or two. Nearly every variety of mother-of-pearl button is manufactured, and the combination of beauty, cheapness, and a fair degree of durability makes competition in the local market extremely difficult. The trade-mark "Affina" is now known in France and England as well as in China and other countries of the Far East.

The factory consists of seven shops, in which the shells, after being steeped in vats for several weeks, are cut, ground, washed, punched, sorted, fastened, and polished. The machinery is entirely of French manufacture (Meru, Oise), or made on the ground after French models. Power is furnished by two 25 h.p. dynamos. The principal auxiliary materials used are stearine, lime, emery, paper boxes, and wrapping paper. The stearine comes from France (or America since the war), the lime is produced locally, the emery comes from France, or a substitute is produced locally, and the boxes and wrapping paper are manufactured in Tonkin.

The operating force consists of a European superintendent and about 350 natives, chiefly women. This number was expected to be increased to 500 by the end of last year. The work is done entirely by the piece. By working 10½ hours a day the men earn 7½*d.* to 10*d.*, and the women 4*d.* to 7½*d.*

Most of the product is consumed in the local market. Flat, round mother-of-pearl buttons are very well adapted to the white linen clothing of the tropics. The extent of the local market, the cheapness of raw material and of labour, and the adaptability of the product to local conditions, promise a good future for this industry.

OBITUARY.

SIR SAMUEL BAGSTER BOULTON, Bt., D.L.—Sir Samuel Bagster Boulton died at his residence, Copped Hall, Totteridge, on April 27th, at the age of eighty-seven.

He was chairman of Messrs. Burt, Boulton and Haywood, Ltd., timber merchants and contractors, of London, Paris, Riga, Salzaette, and Bilbao, and also of the Dominion Tar and Chemical Company, Ltd., and of the British Australian Timber Company, Ltd. He took an active part in promoting the application of scientific methods to chemical and other industries, and contributed to the literature of the subject. In 1884 he was awarded the Telford Medal of the Institution of Civil Engineers.

From 1889–1913 he was chairman of the London Labour Conciliation and Arbitration Board, and presided over the settlement of more than fifty labour disputes. He was created a baronet in 1905.

He had been a member of the Royal Society of Arts since 1882.

NOTICES.

NEXT WEEK.

MONDAY, MAY 13th, and TUESDAY, MAY 14th, at 4.30 p.m. (Cobb Lecture.) HENRY R. PROCTER, D.Sc., F.I.C., Emeritus Professor of the Chemistry of Leather Manufacture, Leeds University, and Director of the Procter International Research Laboratory, "Recent Developments in Leather Chemistry." (Lectures I. and II.)

WEDNESDAY, MAY 15th, at 4.30 p.m. (Ordinary Meeting.) PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

THURSDAY, MAY 16th, at 4.30 p.m. (Special Lecture.) JOHN LEYLAND, "The German Freedom of the Sea." ADMIRAL SIR EDMOND JOHN WARRE SLADE, K.C.I.E., K.C.V.O., R.N., will preside.

Further particulars of the Society's meetings will be found on page 416.

TWENTIETH ORDINARY MEETING.

Wednesday afternoon, May 8th: SIR EDWARD ROSLING, Chairman of the Rubber-Growers' Association, in the chair. A paper on "The Rubber Planting Industry" was read by J. BRETLAND FARMER, D.Sc., M.A., F.R.S., Professor of Botany, Imperial College of Science and Technology.

The paper and discussion will be published in a subsequent number of the *Journal*.

SPECIAL LECTURE ON "THE FREEDOM OF THE SEA IN WAR."

Thursday afternoon, May 9th; LORD SANDERSON, G.C.B., K.C.M.G., in the chair. A special lecture on "The Freedom of the Sea in War" was delivered by SIR FRANCIS TAYLOR PIGGOTT, M.A., LL.M., Chief Justice of Hong-Kong, 1905-12.

The lecture will be published in a subsequent number of the *Journal*.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MAY 15.—PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

MAY 29.—MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

INDIAN SECTION.

HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

[The date will be announced later.]

SPECIAL LECTURES.

The last of the special course of three lectures on "The Freedom of the Sea" will be delivered on Thursday, May 16th, at 4.30 p.m.

LECTURE III.—By JOHN LEYLAND. Chairman, Admiral SIR EDMOND JOHN WARRE SLADE, K.C.I.E., K.C.V.O., R.N.

Syllabus.

THE GERMAN "FREEDOM OF THE SEAS."

Britain the great upholder of the Freedom of the Seas—The meaning of the term—How it was regarded by Grotius—How we came to be denounced as the "tyrants of the sea"—The attitude and policy of Napoleon—His claim to be the liberator from tyranny—The modern German claim a protest against British sea-power—An analysis of the claim—Its real meaning—The view held and expressed in the United States—The agreements and understandings with Prussia—President Wilson's declaration—How it is in conflict with the German claim—The need of a right understanding of the subject.

COBB LECTURES.

"Recent Developments in Leather Chemistry," by HENRY R. PROCTER, D.Sc., F.I.C., Emeritus Professor of the Chemistry of Leather Manufacture, Leeds University, Director of the Procter International Research Laboratory. Two Lectures.

Syllabus.

LECTURE I.—MAY 13.—Structure and chemistry of skin—Processes for removal of hair and epidermis—Removal of lime and preparation for tanning—Use of bacteria and enzymes—Dehydration and separation of fibrils—The pickling process—Nature of colloid swelling.

LECTURE II.—MAY 14.—The conversion of the pelt into leather, and the nature of the change—Tannage with mineral salts—Alumina tannage—Chrome tannage—Vegetable and synthetic tannins—Tannages with aldehydes, quinones and bromine, and with colloidal precipitates—Oil tannage—Summary.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cobb Lecture.) Dr. H. R. Procter, "Recent Developments in Leather Chemistry." (Lecture I.)

Chemists, British Association of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Dr. S. Chapman, "Terrestrial Magnetism."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Mr. J. M. MacLeod, "The Achievements of France in Morocco."

TUESDAY, MAY 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cobb Lecture.) Dr. H. R. Procter, "Recent Developments in Leather Chemistry." (Lecture II.)

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 6.30 p.m. Discussion on "The Lighting, Heating, and Power Order (1918), and the best methods of making Economies."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Dr. J. C. Stamp, "The Effect of Trade Fluctuations upon Profits."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "Field Anthropologists." (Lecture IV.)

WEDNESDAY, MAY 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Dr. P. Groom, "The Timber Industry."

Geological Society, Burlington House, W., 5.30 p.m.

Colonial Institute, Caxton Hall, Westminster, S.W., 8.30 p.m. Paper by Professor McLaughlan (U.S.A.).

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Professor W. M. Bayliss, "Accessory Components of Food."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Lecture by Professor W. L. Courtney.

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Mr. C. E. P. Brooks, "Continentality and Temperature—The Effect of Latitude on the Influence of Continentality on Temperature." (Second Paper.) 2. Messrs. J. E. Clark and H. B. Adames, "Report on the Phenological Observations for 1917."

THURSDAY, MAY 16...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Special Lecture.) Mr. J. Leyland, "The Freedom of the Sea. Lecture III.—The German 'Freedom of the Seas.'"

REGISTERED AS A NEWSPAPER.

NOTICES.

COBB LECTURES.

On Monday and Tuesday afternoons, May 13th and 14th, PROFESSOR HENRY E. PROCTER, D.Sc., Director of the Procter International Research Laboratory, delivered two lectures on "Recent Developments in Leather Chemistry."

On the motion of the CHAIRMAN, a vote of thanks was accorded to Professor Procter for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

TWENTY-FIRST ORDINARY MEETING.

Wednesday afternoon, May 15th; PROFESSOR WILLIAM BATESON, D.Sc., F.R.S., Director of the John Innes Horticultural Institution, in the chair. A paper on "The Timber Industry" was read by MR. PERCY GROOM, M.A., D.Sc., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology.

The paper and discussion will be published in a subsequent number of the *Journal.*

SPECIAL LECTURE ON "THE FREEDOM OF THE SEA."

Thursday afternoon, May 16th; ADMIRAL SIR EDMOND JOHN WARRE SLADE, K.C.I.E., K.C.V.O., R.N., in the chair. A special lecture on "The German 'Freedom of the Seas'" was delivered by MR. JOHN LEYLAND.

The lecture will be published in a subsequent number of the *Journal.*

Journal of the Royal Society of Arts.

No. 3,417. VOL. LXVI.

FRIDAY, MAY 17, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, April 18th, 1918; LORD LAMINGTON, G.C.M.G., G.C.I.E., in the chair.

The paper read was—

WATER POWER IN INDIA.

By ALFRED DICKINSON, M.Inst.C.E., M.I.E.E., M.I.Mech.E.

I have been invited by your Committee to read a paper on "Water Power in India." As a preliminary, I desire to point out that, although I am responsible for installing the largest water-power scheme in India, my knowledge of the possible sources of water available for power in the whole of India is very limited. Therefore I shall not be able to do more than touch the fringe of the subject.

It is, perhaps, desirable to mention at the outset a few elemental, though important, points to be borne in mind before deciding to install water-power, whether in India or elsewhere. Not only industrial, but also agricultural development is now largely dependent upon cheap power. Cheap power is a relative term, and its consideration needs discrimination, for although the cost for power produced from coal at 5*s*. per ton should only be for that commodity one-fifth of the cost if produced from coal at 25*s*. per ton, the relative cost of production may be cheaper by the dear coal. As coal is the chief item of cost for steam-power, so water is the principal item of cost for water-power.

In cost for water-power, interest on the capital expenditure incurred in hydraulic development and the maintenance of the same must be included. Commercially, the permissible capital expenditure on hydraulic development is largely controlled by the cost of coal, or other competing power-producing commodities.

With coal at 5*s*. per ton an expenditure on hydraulic development of, say, one-fifth is permissible as against such an expenditure in a locality where coal costs 25*s*. per ton. Wherever the cost per horse-power is less for coal, or other similar power-producing commodity, than the payment of interest on capital expenditure for hydraulic development and maintenance, water-power becomes a doubtful commercial proposition. A larger expenditure per horse-power on hydraulic developments is permissible where the water is impounded for power and irrigation.

In most manufactured products the cost of power is an important item, but it is of far greater moment to some industries than others, for what would be cheap power to a producer of textiles would be dear and prohibitive power to a manufacturer of aluminium, nitrates, cyanamide, and such-like commodities.

The recent rapid development of electro-chemical knowledge demonstrates that a more world-wide demand exists to-day for cheap power than a short time ago would have been thought possible. The demand for power by electro-chemical industries will justify the development of many sources of water-power which may have been considered thus far of little or no value.

The food problem is a very serious one. This was foreseen by Sir William Crookes when he observed that "As mouths multiply, food resources decrease." This is particularly so as regards India. The land has been for many years cultivated without receiving—in so large a measure as in most countries—assistance from the natural animal fertilisers which have been largely used up, and still continue to be used, as fuel. Therefore, so far as India is concerned, if the mouths are to be fed, the time has arrived when agriculture must be aided. This, in a large measure, can be accomplished by supplying to the earth fertilisers manufactured by cheap water-power.

The abstraction and fixation of nitrogen from

the air is now no longer in an experimental stage. Given cheap electrical energy the manufacture of nitrates is a sound commercial proposition. Electro-chemical knowledge is still in its infancy, but it has progressed sufficiently far to demonstrate that fertilisers can now be manufactured which are of far greater value to the land than the ordinary natural fertilisers, and at a cost to justify their general use.

Various combinations can be made to suit the requirements of any locality. The nature of the earth having been ascertained, the fertilisers necessary to give the best crops can be supplied at a cost which will more than justify the expenditure.

Sufficient has been indicated to show that cheap power is not only desirable for manufacturing industries, but that it is now a necessity for agricultural development. This has been mentioned to draw attention to the great value water-powers may be to agriculture in districts far remote from the manufacturing centres. Many water-powers remain dormant because the cost of transmission to districts where there is a demand for power is prohibitive.

Electro-chemical industries may be established in the vicinity of water-power, thus avoiding capital expenditure on long transmission lines.

Before considering possible water-powers it may, perhaps, be more interesting first to give a few particulars of one or two of the schemes already developed. The most important scheme thus far is that of the Tata Hydro-Electric Power Supply Company. It is frequently said that engineers lack imagination, and that there is no such thing as romance in engineering. I believe that the Tata Hydro-Electric scheme disproves these statements. The general impression is that water-power is the utilisation of the water of existing rivers or lakes. The Tata Hydro-Electric undertaking is not of that character; it is a scheme to provide, approximately, 100,000 water horse-power from valleys which have from time immemorial been dry for nine months of the year, and where no water had been previously stored. The valleys were so dry that one of the initial difficulties in converting them into lakes was to provide water for use in building the masonry dams.

When the scheme was in process of development I was advised by engineering friends not to risk my reputation by being associated with "such a perfectly absurd engineering proposition," and on generally accepted engineering principles I admit that if the scheme had been placed before me for advice I should have reported against it. Many looked upon the question, not as a serious engineering proposition, but as a fairy tale. But even in engineering the exception proves the rule. The Tata Hydro-Electric scheme can only be justified on that ground. This will be appreciated when it is stated that, even after the work of building the dams had been in hand for some very considerable time, the Company were advised that the supply of water would be insufficient because the catchment area could not yield water to fill the lakes.

Those versed in these matters will agree that the engineer did not lack confidence who advised that rain falling during the monsoon on a total catchment area of 22 square miles would be sufficient to enable, roughly, 100,000 water horse-power to be developed for 3,600 hours in each year, but it was confidence begot by experience and knowledge, and now justified by results. The catchment area is exceptional to the extent that almost all the water falling runs off.

Mr. R. B. Joyner, C.I.E., who had special knowledge and long experience of this district, made the detailed investigation of this part of the scheme, and it was upon the results of his investigation that I relied.

His report showed that on the eastern side of the crest of the Western Ghats, the rainfall was not only enormous in quantity, but in intensity also.

Rainfall.

It was demonstrated that it was rare for the annual rainfall to be less than 12 ft., that generally it was from 18 to 20 ft., and that occasionally it was 26 ft., this enormous quantity falling within four months. Twelve inches is not unusual, and as much as 20 in. have been known to fall in twenty-four hours. The average fall per day in forty-five days for thirty-four years was about $3\frac{1}{4}$ in.

It has since been demonstrated that approximately 90 per cent. of the rain falling on the catchment area is caught and stored. The investigations covered a period of thirty-four years, and during that period the maximum rainfall was 320 in., the minimum 90 in., and the mean approximately 200 in.

The care necessary, and the experience needed, to arrive at reliable results, is demonstrated when it is pointed out that rain-gauges placed less than half a mile distant from each other showed that the quantity of rain falling on the areas checked varied enormously. The readings

of the rain-gauges during one monsoon of ninety days showed that, whilst rain falling in the valleys approximated to 250 in., during the same period a gauge on the top of one of the hills registered no less than 540 in. So far as I am aware this is the highest recorded rainfall *in the period* throughout the world.

Lakes and Dams.

Three large lakes have been formed by constructing dams across three valleys, known as Lonavla, Walwhan and Shirawta, the hearting of the dam being of uncoursed rubble masonry, and the facings of coursed rubble masonry.

The Lonavla Dam is 3,600 ft. long, and 40 ft. high from the bottom of the foundations. The Walwhan Dam is 4,500 ft. long, and 75 ft. high from the bottom of the foundations. The Shirawta Dam is 8,000 ft. long, and 100 ft. high from the bottom of the foundations. The Shirawta Lake is connected to Walwhan Lake by a tunnel 5,000 ft. long through the hills. The water to the tunnel is regulated by sluices fixed in a headwall at the Shirawta end of the tunnel.

From these lakes water is conveyed in an open duct, roughly four and a half miles long, having a capacity of 120,000 h.p., to the forebay. The forebay has a storage capacity of about one and a half hours for the whole of the eight sets working. Openings are provided in the dam of the forebay for three 82-in. pipes.

Pipeline.

From the forebay is a steel pipeline, which carries water down the steep slopes and cliffs to the power-house at Khopoli in the plains below. The pipeline has been designed in two sections, namely, for two upper and eight lower pipes. At present there are installed one upper and five lower pipes. The pipes are laid above ground, proper provision being made for variations of temperature by expansion joints inserted between fixed points in the upper pipeline, and at each thrust block in the lower pipeline.

Power-house.

The full scheme is for a plant capacity of, roughly, 96,000 h.p., divided into eight main sets of 12,000 h.p. each. In addition, there are two 850 h.p. exciter sets, eight step-up three-phase 10,000 k.v.a. transformers, each bank consisting of three single-phase transformers, with the necessary switchgear, station auxiliary apparatus, and four outgoing transmission lines. The main generating sets are impulse turbines of the horizontal type, running at 300 revolutions per minute, direct-coupled to the three-phase enclosed self-ventilating generators.

Some idea of the size of the transformers will be gathered when it is stated that, filled with oil, each weighs 24 tons. It takes eight tons of oil to fill each transformer.

The switchgear system is arranged for operating each unit with its own transformer bank. The high-tension oil switches are for automatically tripping by inverse time limit overload series relays. All auxiliaries are operated by three-phase current, 440 volts, and all the high-tension switches are operated by remote control.

Transmission Line.

The route of the transmission line is from the power-house at Khopoli to the receiving station on the Island of Bombay, a distance of forty-three miles. The line crosses two tidal creeks (one of which is 10,000 ft. wide, and 42 ft. deep at high tide), a railway, and several roadways.

Two change-over stations are provided, each with air-break disconnecting switches, which divide the line into three sections for cutting out or interconnecting different sections as required.

Stranded copper conductors are used, and are placed 10 ft. 6 in. apart.

Receiving Station.

The receiving station is situated at Parel on the Island of Bombay, and has a plant capacity to deal with the output of the power-house. The switchgear system consists of remote control electrically operated oil switches and other apparatus.

The feeder system from the receiving station to the mills is designed for a 6,000 volts, 50 period, three-phase supply, with an unearthed neutral. The cables are of the three core paper, insulated lead covered type, and are laid on the solid system in between in earthenware troughing about 18 in. below the footway.

For the purposes of the feeder system, the cotton-mills are arranged in groups, there being a feeder to each mill with an emergency ring feeder connecting up all the mills of the group.

Mill Equipments.

The problem presented by the cotton-mills of Bombay was the conversion from mechanical to electrical drive, utilising the existing shafting,

and the change to be effected with as little interference as possible with the production of the mills. The problem was thoroughly investigated and, after consideration, group-driving with direct-coupled motors was adopted as being best suited to the requirements of the Bombay industry. Standard speeds of 265, 290, and 365 revolutions per minute were adopted.

The motors are of the slip-ring induction type, wound for 2,000 volts, provided with the slip-ring and brush-lifting and short-circuiting gear enclosed, and are standardised to about six mechanical sixes for renewals and spare parts, and in windings ranging from 30 to 500 h.p. They are designed for driving from either end of the shaft. The full load efficiencies range from 87 to 92·5 per cent., and the full load factors from ·74 to ·84. The starting switches are of the liquid type, the electrodes being operated through slow-motion gear. In the case of callender machines, special starters are supplied to meet the conditions of service.

The mill transformers are of the three-phase, 6,600–2,200 volts, 50 period, oil insulated, air-cooled core type, star connected on both sides, and are provided with an earthing device. They are supplied in four sizes, 500, 600, 700 and 900 k.v.a., from which the power requirements of each mill are met. They have at full load, and a power factor of ·80, an efficiency of about 98 per cent., and a regulation of 2·4 to 2·7 per cent.

As a result of the adoption of electric drive, I have been informed that a much better yarn is produced, and, in addition, with the same textile machinery the output has been considerably increased.

The satisfactory supply has increased the demand for power beyond the capacity of the present plant installed, with the result that in order to meet it other works and plant are now under construction, known as the Andhra Valley Electric Supply. It is anticipated that, when completed, this plant will enable the company to meet all the demands likely to be made by Bombay in the near future. Contracts have already been entered into for approximately 100,000 h.p. The price per unit is ·5 of a penny, and when it is borne in mind that coal in Bombay is, roughly, three times more costly than in England, it will be seen that this is a very low charge.

Important as are the advantages derived by the textile industry of Bombay, they are small when compared with the enormous benefits the population of that city derive by the abatement of the smoke nuisance. Already smoke from some forty chimney-stacks has gone, and it is hoped that shortly it will disappear from all of them. Those who know Bombay will appreciate how much more agreeable life will be in that city when the dense palls of smoke which overhang it vanish.

So far as I have been able to ascertain, the first hydro-electric system in India was the small plant of the Darjeeling Municipality, installed in 1896. Prior to the installation of the Tata hydro-electric system, the most important scheme was that of the Mysore Government at the Cauvery Falls. This scheme was decided upon about 1897, and energy first supplied in 1902. The original scheme contemplated the installation plant of 6,000 e.h.p., the electrical energy generated being transmitted to the Kolar Goldfields to replace in part the steam-power used by the mines, the transmission voltage being 30,000 volts. Extensions have been made, so that at the present time the power-house has a capacity of 22,650 e.h.p. Power is transmitted to the mines at 78,000 volts, and to the cities of Bangalore and Mysore at 35,000 and 22,500 volts respectively. Electrical energy is generated at 2,000 volts. The transmission line to the mines is ninety-two miles in length, this being in duplicate. Bangalore is fifty-seven miles and Mysore thirty-seven miles from the power-house.

By drawing the water from the river about two miles above the falls, and conducting it through an open channel about 17,000 ft. in length to the power-house, about one mile below the falls, a head of 405 ft. is obtained. During the months of February, March, April and May, the normal discharge in the river falls below requirements. Consequently a reservoir of approximately 37,000 m.c.ft. storage capacity is being constructed at Kushmaraja Sagara. This reservoir is on the Cauvery River near to Mysore. Provision has been made for four penstocks in the reservoir dam. When the dam is completed to its final height, 4,000 e.h.p. can be generated and fed into the present system at Mysore city.

The State of Patiala possesses a small installation for city lighting.

There is a hydro-electric station of moderate size on the Bhatti Nadi. The power here generated is transmitted to Mussoorie and Dehra. The power-house is situate 7½ miles from Mussoorie and contains generating plant of 1776 k.v.a. capacity. The minimum dis-

charge of the stream is about 9 cubic ft. per second. The pipeline consists of two lines of mild-steel pipes. It has a total length of 4,350 ft., and a varying diameter of 16 in., 14 in. and 12 in. The total fall in the pipeline is 992 ft. High-tension lines are run to Mussoorie and to Dehra, 6,600 volts pressure. There are fourteen substations in Mussoorie, and five in Dehra. Distribution is carried out on a low-tension system for lighting purposes in the two towns named, and for pumping water for the supply of Mussoorie.

Simla is now supplied with electrical energy generated by water-power.

In the Native State of Kashmir and Jammu, water-power plants have been installed on the river Jhelum and at Jammu. In the case of the Jhelum installation, water is obtained from the Jhelum River, the power-house being at Mohora. The hydraulic works and pipeline arrangements carried out up to the present have a total capacity of 20,000 h.p. Water is conveyed a distance of six and a half miles from the river to the forebay by means of a timber flume 8 ft. 4 in. wide by a depth of 8 ft. to full supply level.

The forebay is arranged for eight intakes, of which four have been provided with steel pipelines. Each pipeline is 600 ft. in length, and there is a total vertical head of 405 ft. from the forebay to the turbine, with an effective head of 395 ft. The arrangement of valves on the pipelines is such that any one unit can be served from either of the pipelines.

The power-house plant consists of four vertical turbines, each direct-coupled to a 1,000 k.w. three-phase 2,300 volts, 25 period, generator running at 500 revolutions per minute, each unit being capable of sustaining an overload of 25 per cent. for two hours, and two exciters each of 150 k.w. capacity, and capable of exciting 5,000 k.w. of generator capacity. There are two banks of transformers, each of 3,100 k.w. capacity at 2,300 volts primary, and 60,000 or 30,000 volts secondary, with an additional tapping for 50,000 volts. The transformers are oil-immersed and water-cooled, and are delta-connected in each bank. The transformers are operated through remotely controlled oil switches.

There are two outgoing transmission lines from the power-house. These are run side by side as far as Baramula, twenty-one miles distant, at which point one terminates, while the other is continued to Srinagar, a further thirty-four miles. Each transmission line consists of three conductors of six strand No. 10 Brown and Sharp gauge copper mounted on 60,000 volt insulators, pin type, and is carried upon timber structures.

A metallic circuit telephone line is run upon the same poles as the transmission line, and is connected to telephone instruments at about every ten miles of the line. Induction troubles were experienced with this line, but these have been overcome by transposition of the E.H.T. conductors. Galvanised iron wires earthed at every pole are run the whole length of the lines, and fastened to the top cross arms as lightning conductors.

At Baramula and in its vicinity there were originally three floating substations, each containing one bank of three 200 k.w. step-down transformers—1,800 k.w. in all—this supply being used for the working of dredgers and dredger derricks, and the supply of light to the town of Baramula. The E.H.T. line to Srinagar has been tapped near Sopore, at a distance of about seven miles from Baramula, and light supplied to that town.

The line has also been tapped at a point halfway between Baramula and Srinagar, and a three-phase line is run for a distance of fourteen miles to Gulmarg. The supplies given at the three before-mentioned places are small.

At Srinagar the transmission line terminates in a silk factory substation, in which there are installed five 500 k.w. 60,000–30,000 to 2,300 volts transformers. The silk factory calls for a load of 1,700 k.w. From this substation a 2,300 volts transmission line has been run to Basant Bagh, where public lighting is carried out, the maximum load being 450 k.w.

The hydro-electric installation for the generation of electrical energy for supply to the city of Jammu is situate on the Irrigation Canal. There is but a low head of 26 ft., and the plant installed is 772 k.w. There is an overhead transmission line at 3,000 volts. The output of power is principally utilised in connection with the Maharaja's palace, the waterworks, and the lighting of the city.

Hydro-electric power has even penetrated into far-off Afghanistan, where the Amir has had installed a small plant for supplying light and power to Kabul.

The Governments of Canada, New Zealand, Tasmania, and the United States realise how important water-power is to their respective countries, and have had elaborate surveys made showing the location and particulars of the more important water-powers. This enables those interested to ascertain what powers are

available for development without incurring the heavy expense of preliminary surveys and local investigation. The question of water-power to these countries is relatively unimportant compared with India; in India, not only is cheap power important, but water for irrigation is in many cases vital.

My view is that the Indian Government should at once undertake a complete investigation of the possible sources of water-power in the country, and that the information thus obtained should be available for public use. Perhaps this will follow as a corollary to the investigations of the Industrial Commission.

Private enterprise has already done much, and is doing more. Messrs. Tata, Sons and Co., Bombay, have been the pioneers, and continue to lead the van. As a result of investigations made at their expense, it can now be demonstrated that, by constructing a dam across a valley in the Western Ghats, water from the Koyna River can be harnessed so as to provide approximately 300,000 h.p. continuously. The preliminary estimates of cost show this scheme to be a thoroughly sound commercial proposition.

In my opinion this is a discovery of the highest importance to the whole of the East. If a Niagara had been announced the world would have been agog, perhaps more from a spectacular than a power-producing point of view. When the possibility of supplying 300,000 h.p. for every hour in the year is appreciated, it will be seen that it is equivalent to supplying to industries during the normal working hours of 3,600 per annum no less than 730,000 h.p. for each and every working hour of the year.

Consider the possibilities this creates. Seven hundred and thirty thousand horse-power for ten hours each day for 360 days in each year supplied at, say, one-third of a penny per horse-power hour. This should give to India the greatest industrial fillip she is ever likely to receive from any single discovery.

I am investigating the possibility of utilising for power purposes the irrigation lake at Periyar, in the Madras Presidency. So far the investigations show that a thoroughly workable and commercial scheme for the manufacture of nitrates on a large scale can be established. The dam, lake, tunnel, and other works in connection therewith were fully described by the late Colonel J. O. Hasted, R.E., in the paper read before this Society on April 30th, 1891.

I am aware that power can be obtained from the Bari Doab Canal and the Dudh Sagar Falls, and I have every reason for believing that very considerable power can be secured in many parts of India. My departure for India, together with the pressure of business, precludes the possibility of my going into details.

The advantage of water-power development in India will be apparent to those interested in, or who appreciate, the industrial awakening of that vast Empire, for water-power development can, and will, materially hasten that awakening.

The rapidity of industrial and agricultural development will, in my view, be largely dependent upon a closer union between the East and West.

India possesses in abundance the necessary minerals for metallurgical development; the climate and land needful for the cultivation of cotton, flax, jute, and many other commercial commodities; and an enormous and intelligent population which, if properly trained, will provide skilled workers in great numbers. In addition, its available capital is substantial.

Although much has been done, her industrial possibilities, to use a vulgarism, have scarcely been "scratched." It is well known that not infrequently the obvious is overlooked. My view is that so far as the captains of finance and industry in the West are concerned, they have not been altogether ignorant of the industrial possibilities in India, but hitherto have not shown the necessary confidence by taking part in our helping forward rapid development. They had an opportunity to finance and construct the Tata hydro-electric scheme, but failed to appreciate its importance. It was therefore left to India to find the requisite capital, to the great advantage of the Indian investor, for this is the only electrical undertaking of magnitude which, in the first year of its working, has earned and paid a dividend on its full capital; and, although it is as yet incomplete, it is earning a profit of over £190,000 per annum.

[Owing to the absence of Mr. Dickinson in India, the paper was read by Mr. E. S. Woollard Moore, Assoc.M.Inst.E.E.]

DISCUSSION.

The Chairman (Lord Lamington) said that not very long ago he had the honour of presiding over a meeting of the Society when a paper dealing with the great Tata iron and steel works in India was read, and he remembered what a wonderful undertaking was then revealed. On the present occasion everyone present must feel that he had

been listening to another fairy tale in revelation. There were one or two points that he would like Mr. Moore to explain more fully. For instance, referring to the main scheme, the Bombay scheme, it was said in the paper that the catchment area was exceptional to the extent that almost all the water falling ran off, and he did not quite understand the meaning of those words. Also, could Mr. Moore account for the fact that the yarn was much better when the motor power used was electricity. He would also like to know whether the pipe track of two and a half miles with a fall of over one thousand seven hundred feet, was not almost a world record. It was stated in the paper that the Tata Hydro-Electric undertaking provided 100,000 h.p., and in comparison with that it would be interesting to know what was the power derived from the Niagara scheme in Canada. It was very satisfactory to think that already the supply, great as it was, had been overtaken by the demand in Bombay City. He understood that the scheme was not yet in full operation, and he would like to know whether the proposal to use the Andhra water-supply was to be in connection with the Bombay scheme or quite a distinct undertaking. He was glad to learn that not only were the industrial benefits derived by Bombay from the Tata Hydro-Electric undertaking such a great blessing, but that Bombay had been relieved of the smoke that had disfigured what was in his opinion one of the most majestic and beautiful cities on the face of the globe. With regard to the remark in the paper that the rainfall varied considerably at places within half a mile of one another, he was reminded that at Mahableshwar the rainfall was over three hundred inches, whereas it was only sixty inches at Panchgani, eleven miles distant, showing the effect that difference of altitude had on precipitation. In the Koyna Valley there was a tremendous quantity of water flowing to waste, and there were many waterfalls in the Bombay Presidency, and perhaps still further south, which in time to come might be utilised for the development of power. He agreed with the author that it would be very advantageous if the Government of India had a complete survey made of all those possible sources of supply, which ought not, in his opinion, to be worked by the Government, but by private people. He did not quite agree with the remark of Sir William Crookes quoted in the paper that "As mouths multiply, food resources decrease." Two or three hundred years ago the population of this country was very much smaller than at present, but the food supply had increased out of all proportion to the increase in population. He thought the increase of population was rather dependent upon the increase of food supplies. In these days, when human enterprise and intellectual power had developed in such a marvellous fashion, of which an instance was given in the paper, it was a very sad reflection that at the present moment all the resources of human ingenuity were being devoted to the destruction of all that had been built up in the past.

Sir Charles H. Armstrong said the subject of the paper was a very interesting one to those who had lived in Bombay, as he had done for thirty years. He remembered the discussions that took place when the Tata Hydro-Electric scheme was under consideration. It was stated in the paper that it was then looked upon as a perfectly absurd engineering proposition, and he believed the reason was that it was thought the trap-rock would not hold the water. He was astonished, however, to learn that, after the work of building the dams had been in hand for a considerable time the Company were advised that the supply of water would be insufficient because the catchment area could not yield water to fill the lakes; and he thought everyone who knew the ghats round about Bombay and the enormous rainfall of that mountainous district would be surprised that that point had ever been raised. He was pleased to hear that the smoke nuisance in Bombay had been to a very great extent abated by the scheme of the Tata Company. Twelve or thirteen years ago, when the Port Trustees of Bombay were making their annual inspection, Lord Lamington was their guest, and seeing the smoke lying over Bombay, he expressed the wish that something could be done to remove it. It had now been removed to a great extent, and he was very glad to hear that so many mills had adopted the electric drive. He remembered, however, that just before the Tata Hydro-Electric scheme was started he happened to be a director of one of the largest and best-equipped cotton-mills in Bombay, and when the question was raised as to whether the steam drive or the electric drive would be the cheaper the engineers of those mills advised the directors to continue working by steam. There was no doubt that at the present time, certainly in Western India, electrical power was a very important matter, one of the reasons for that being that the cost of Indian coal was steadily increasing, and that in the future the coal was likely to be a great deal more expensive than it was before the war. Bengal coal before the war used to come to Bombay by sea, but now it had to come overland by rail, which was costly, and its transport had seriously interfered with commercial traffic and also, to a certain extent, with military traffic. He happened to be connected at the present time with the Great Indian Peninsula Railway, which, with the Bombay-Baroda Railway, served Bombay, and had a very large suburban traffic. It would be a very great advantage if that traffic could be worked by electricity. It would be an advantage also if the ghat traffic of the Great Indian Peninsula Railway could be worked in the same way. At the present time the Great Indian Peninsula Railway had a very large scheme under consideration; an engineer was investigating the matter in India, and no doubt, sooner or later, that railway would adopt electricity on a very large scale. In and near Bombay it would probably use water-power, the water being obtained from the ghats in the same way as the Tata schemes were now being worked, and the

Company might possibly work in conjunction with the Tata Company. The railway was also considering the possibility of using oil, which was certainly cheaper than coal, and it might be that in and near Bombay it would be found cheaper to use oil than electrical power. Electrical power, however, had a very great future before it in India, and if the money was forthcoming—as it certainly ought to be, because India was very prosperous—it would be possible in the near future to make very great headway in that direction.

Mr. C. H. B. Burlton said the paper was most opportune. The British Administration in India had been very conservative in some respects, which was the reason why many of the developments now taking place had not been carried out before. Probably the first of the hydro-electric schemes set on foot was that alluded to in the paper, the Cauvery Falls scheme. He remembered in the late nineties being shown over the works that were then being started in connection with that scheme by Colonel McNeill Campbell, the chief engineer of Mysore. The works were conducted under Colonel Campbell's auspices, and were under the direct execution of Colonel, then Captain, de Lotbinière, who had made his mark in the engineering world in India. It was very encouraging to note that there were many works of a similar nature now in existence, and that water-power had been used for the generation of electricity. There were, however, many cases where water was being allowed to go almost to waste. For instance, the Nilgiri Railway was constructed after engines were first run by electricity, and although that line had been in existence for about twenty years it was still run by steam, and the enormous amount of water-power in that district was therefore going to waste. The Kateri Falls, for example, were unharnessed and within easy distance of the Nilgiri Railway. It was a great pity that that railway was still worked by steam, because of the expense of bringing coal such a great distance, there being probably no coal worked much south of Bengal. About twelve years ago there were five high masonry dams in India, and he did not think any of them had yet been harnessed for the purpose of transmitting power over any distance to supply towns with electricity or for the benefit of works. Progress was now being made in connection with such matters, however, and the paper showed that India might soon pass from industrial infancy into industrial adolescence or even manhood. It was very important that the resources of the country should be utilised in the country itself. There was a very great need for fire-bricks in India at the present time, and they were now being imported in very large quantities, but he believed that if they were manufactured in the country, then, with hydro-electricity available, the prosperity of India might be ensured industrially as it had been already ensured agriculturally.

Mr. Alph. Steiger, M.Inst.C.E., said that one of the first water-power installations was that developed at the cotton-mills at Gokak, in the Bombay Presidency, in 1885. At that time practically nothing was known about electrical transmission, and there the power—amounting in all to 750 h.p.—was transmitted by wire ropes from the bottom of the cliff to the top and along a few hundred yards to the mills. Seven years after that the electrical transmission plant at Frankfort was developed, and proved to be a success, and when the mills at Gokak required more power the question arose whether electricity could not be applied there, but the idea was abandoned, as at that time not sufficient experience was available as regards the influence of the climate, monsoon, and thunderstorms on electrical transmission. The plant was extended to 2,000 h.p., again using the wire-rope transmission; but a few years ago the whole of the transmission plant was scrapped and the electrical system adopted, which had proved a great success, the whole of the machinery in the mills being driven by electricity. The next hydro-electric installation was the Cauvery power-plant, which he had the honour to design, and that plant showed the progress that had been made within the last decade or so. The fall there was about 300 ft., but the units were not larger than 1,250 h.p. each, whereas if the same plant were to be installed now units would probably be adopted of 3,000, or perhaps 5,000 h.p. He ought to mention, however, that at that time the total power from the Cauvery River was not so great that it would have justified so large a unit; but still, instead of six units of 1,250 h.p., two or three units of 3,000 or 4,000 h.p. might have been put in at considerably less cost. The second extension of that plant, made a few years afterwards, was again composed of 1,250 h.p. With regard to the question of producing nitrogen from the air, that question had been raised by Colonel de Lotbinière, and the conclusion come to was that it would be too expensive. The idea was to produce cyanamide, a combination of nitrogen with carbon, but at that time carbon could only be produced in India at great expense, owing to the lack of coal. Since that time coal-mines had been developed in India, and cyanamide, which would be an exceedingly suitable fertiliser for certain soils in India, might well be produced there. It was noticeable that all the plants which supplied large powers in India were in the hilly or mountainous districts, where they required electrical transmission to a considerable distance and at great cost, and he thought there were water-powers in the lower parts which could be developed. He had been connected with one, but there the power varied greatly, and in the dry season only about 400 h.p. would be obtained, which might be sufficient to supply towns with light and power to work the trams, but would not be sufficient for supplying the factories at that locality all the year round with the required power. Some

system might be arranged by which the high-fall power plants in the hilly districts could supplement the installations in the lower districts when necessary. In one case in Switzerland a plant that produced 55,000 h.p. under high fall supplied current to another plant about sixty miles off, where the fall was only about 30 ft., the two systems together supplying a large industrial district with power. Some method of that kind might be adopted with advantage in India. With regard to high falls, the question was often asked as to what was the highest fall that could be utilised in one stage. At one place in Switzerland turbines had been installed that utilised a fall of 5,000 ft., and the same might be done in India, but for such a tremendous pressure pipe-lines were required that could not be produced in the ordinary way. With reference to the fact mentioned in the paper that power was supplied in Bombay at ½*d*. per unit, it would be interesting to know what the capital outlay per horse-power delivered at Bombay would be, because the charge of ½*d*. per unit was remarkably low.

Major-General Beresford Lovett, C.B., C.S.I., said he would like to know why the author dismissed the very successful scheme of electrification at Simla in two lines and yet devoted several paragraphs to the Mussoorie scheme. Moreover, there was no mention in the paper of the Darjeeling scheme and other schemes which were in operation at the present time; and, with regard to prospective schemes, nothing was said about the Jumna scheme, which proposed to supply Delhi with electric power, or alternatively to work iron-mines within a mile of where the proposed central station was to be.

Sir Murray Hammick, K.C.S.I. (Member of the Council of the Secretary of State for India), proposed a vote of thanks to Mr. Dickinson for his interesting paper, and to Mr. Moore for reading it. With reference to Mr. Burlton's remarks, in which he cast rather a slur on the Madras Presidency for not having electrified the Nilgiri Railway, and said that the Kateri Falls should be used for the purpose, apparently Mr. Burlton was ignorant of the fact that those Falls were already harnessed for the very large cordite factory that had done such splendid work during the war. The Kateri Falls had been harnessed for several years, and supplied the power to run all the machinery of that great cordite factory. He knew that the electrification of the Nilgiri Railway had been on the *tapis* for a very long time, but a great scheme such as that required a great deal of consideration. Another large scheme in Madras was connected with the Periyar works, and there now appeared to be some prospect of its being carried out. It was an extraordinary thing that the immense fall of water that came down from the splendid irrigation lake at Periyar had never been used for the production of power. He felt certain that, as the outcome of the energy displayed in the matter by Sir Thomas Holland, the Government of India would seriously undertake the thorough hydrographic survey of the whole of India with regard to electric power which had been wanted for so many years past. The ignorance of the hydrographic conditions of India had stood in the way of all the schemes that had hitherto been brought forward, and those who had travelled from Madras to Bombay would appreciate the tremendous amount of power that was being wasted on the ghats—a waste which it was hoped might soon come to an end.

Sir Francis Younghusband, K.C.S.I., K.C.I.E., in seconding the motion, said the paper was a very interesting and valuable one, and ought to have a great effect on the future development of India. He hoped the meeting would endorse the proposal made in the paper that there should be a thorough investigation made of the water-powers of India—a proposal which had already been endorsed by the Chairman and Sir Murray Hammick. It was exceedingly important that such a survey should be made, because of the tremendous possibilities which lay before India in the development of its water-power. He was Resident in Kashmir at the time when Colonel de Lotbinière carried out his great work of installing electric-power on the Jhelum River. He had many conversations with him with regard to the development of water-power in India, and Colonel de Lotbinière pointed out the possibilities latent in the water-powers of the Himalayas. The present paper referred chiefly to the water-power from the ghats in Western India, but, of course, in the Himalayas there were even greater potentialities. Any one who had seen the great rivers coming down from the Himalayas would feel appalled at the idea of tackling such tremendous torrents, but only a few days ago he was reading in an American engineering journal of a scheme which had been put before the New York State for harnessing the Niagara Rapids below the Falls, the idea being to spend no less than £20,000,000 in making a dam right across the river and obtain 2,500,000 h.p. from that. No more difficult scheme than that could be undertaken in the Himalayas, and to tackle the Indus itself would not be a greater task than tackling the Niagara. If the great rivers that flowed down from the Himalayas could be harnessed, the railway systems which ran along the fertile plains at the foot of the mountains could be electrified, and power could also be provided for the electro-chemical processes for the ironworks and great factories that were springing up in India now. It was, therefore, exceedingly important that the Government should undertake a systematic survey and investigation of the water-powers of India, not only in the Himalayas but in the Western Ghats, in Central India and in Assam. If that could be done without delay, then private enterprise, both in this country and in India, could set to work on the task of utilising the water-powers of India.

MR. E. S. WOOLLARD MOORE, in replying to the discussion, said that, in reference to the question raised by the Chairman as to the meaning of the statement that the catchment area was exceptional to the extent that almost all the water falling ran off, the author meant that the water found its way from the catchment area into the lakes and did not percolate away or become dispersed in the ground. As to why the yarn was better when the motive power used in its production was electricity, he thought the reason was that the electric power gave greater uniformity in driving. With regard to the point raised that the author had omitted to mention many important schemes, it was stated in the paper that he only dealt with those that had come more or less within his own knowledge, and further a good deal of matter sent home from India had not arrived. It was stated in the paper that the Tata scheme at Khopoli was earning a profit of over £190,000 per annum at ½*d.* per unit, which showed that the capital expenditure was not incommensurate with the results that had been achieved. As to Niagara Falls, he believed the two power-houses on the American side and the one on the Canadian side had a present aggregate of about 285,000 h.p. The height of fall at Khopoli was not unique, but although there were higher falls harnessed, their installed loose power was less. Nature had been kind to the Khopoli scheme in providing a site for the forebay at a height above the power-house of some 1700 ft. only about 2½ miles distant. He was glad the Chairman had mentioned the paper read by Mr. Tuckwell on January 17th, because that paper gave records which were of historic importance. It might be of interest if he stated that the aggregate horse-power of the three schemes of Messrs. Tata—the Khopoli, the Andhra Valley and the Koyna River schemes—was over half a million continuous horse-power, or about one million horse-power on a ten-hour day basis. The Khopoli scheme was actually at work, the Andhra Valley scheme was in course of construction, and the Koyna River scheme, the largest of them all, was being closely investigated and studied. Their capacity exceeded the aggregate horse-power of steam turbines installed at the present time in the whole of the United Kingdom, and was practically equal to one-tenth of the aggregate horse-power of all kinds of power-engines in the United Kingdom. It was somewhat difficult to realise what such huge super-power stations meant. Taking a station of 300,000 h.p., such as the proposed Koyna River station, if that were a steam station operated for twenty-four hours per day with the best efficiency turbines and steam-plant that engineers knew of at the present time, it would need 30,000 to 35,000 tons of good quality coal per week, and as all the coal raised from a mine would not be suitable for power-house consumption it would not be unfair to say that a steam station of that size would require the output of at least two modern collieries. As the price of coal in India was rising faster than the interest on capital was rising, the disparity between water-power development and steam-power development was rather tending to increase. He thought that coal could be more usefully employed in the development of industry in India in the way of actual direct manufacture than in the production of power. Another point of comparison was that the storage capacity for a 300,000 h.p. steam-station in the matter of coal was a point of considerable importance when coal was being used at the rate of 35,000 tons a week. The amount of ashes that would have to be disposed of would be about 5,000 tons a week. The condensing for a station of that size—a problem far more difficult in the tropics than in a temperate climate—would require about 25,000,000 gallons of water per hour, which was the flow of quite a large river. So that the comparison between water-power and steam-power in India seemed to tend enormously in favour of water-power, and cheap water-power for India was no idle dream, but a realisable proposition.

The resolution of thanks was carried unanimously, and the meeting terminated.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 17th, 1918; J. AUGUSTUS VOELCKER, M.A., Ph.D., Member of the Council of the Society, in the chair. The paper read was "Agricultural Machinery," by FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England.

The text of the paper was printed in last week's *Journal*. The following is the discussion on the paper:—

DISCUSSION.

THE CHAIRMAN (Dr. J. A. Voelcker), in opening the discussion, said the author had dealt with the subject in a very comprehensive and interesting manner. It would be a matter of satisfaction to all members of the Society present to hear that the Royal Society of Arts was the first to offer prizes for agricultural machinery, and that as long ago as 1812 it offered a medal for a reaping-machine. When the Royal Agricultural Society was founded it took over that work, and trials of agricultural machinery were now being conducted by that Society, of which Mr. Courtney had been for many years the Consulting Engineer. The author had described the history of the development of agricultural implements, and it appeared that he thought for ploughing land the steam plough would still take a lot of beating, despite the advent of motor ploughs and tractors. There were three or four points in the paper that had especially struck him. One was that there was a great deal of good in old things. When one saw that wooden ploughs were still used in some parts of

the country one felt there must be some good reason for it. Then a number of old things that had been discarded had been brought up again, as, for instance, the double-furrow plough. There had probably never been a time when the double-furrow plough had come into such extensive use as during the past year, when so much land had had to be ploughed up. Next he had been very much struck also by the new implements that had been invented, such as the disc cultivator and the disc plough, and which had done really wonderful work in turning up old grass-land. Lastly, he noticed that agricultural machinery had not, as yet, been brought to a state of perfection, as was instanced by the fact that at the present time there was not anything like a perfect farm-yard manure distributor. It was very difficult to understand the reason for one kind of implement being used in one part of the country and another kind in another part. Taking, for example, one point to which the author had referred, the methods of elevating hay: in the south of England the hay elevator was universal, but in the north the Marston fork was always used. He had had many discussions with his agricultural friends in both the north and south of the country as to the reason for this, but had never yet been able to find out the real cause. It would be very interesting to know whether there really was a reason, or whether it was merely the outcome of custom. All these points led to the general conclusion that in the future there would be renewed interest and importance attaching to the trials of agricultural implements, and he was sure that both the Royal Agricultural Society and the Royal Society of Arts would play their part in encouraging the development of agricultural machinery.

Professor William Somerville said that the war had caused special attention to be paid to agricultural machinery during the last few years. He served on the Agricultural Executive Committee of the County of Oxford, and the task put before that Committee by the Board of Agriculture of finding a certain number of thousand acres of newly-ploughed land would have been a great deal more difficult if it had not been for the advent of the tractor plough, the value of which was still under-estimated by many people, but which, in the hands of good workmen and used on reasonably suitable ground, did marvellously good work. With regard to the double-furrow plough, he remembered that twenty-five or thirty years ago that plough was very little used, but it had recently been very much developed. To comply with a ploughing order served upon him in a county in the south of England, he had purchased a double-furrow plough, which had done very satisfactory work. With reference to the remark made by the Chairman about one implement being used in one part of the country and another implement in another part, he thought the climate had something to do with the fact that the horse fork was used in the north of England and the elevator in the south. In the south the hay could more frequently be carted straight out of the wind-row, and in many cases, by means of hay sweeps, could be brought right up to the foot of the elevator, pitched on to it, and taken up to the stack with a minimum of trouble; but in the north the hay was rarely in such good condition as to be taken straight out of the wind-row on to the stack. He used to doubt whether there was any truth in the stories one sometimes heard about the spontaneous combustion of hay. In 1911 he put basic slag on to his land, which stimulated a great mass of clover, and the hay was probably carried rather too early, having regard to the clover. Possibly the horse fork dropped it in rather large lumps on the stack and it was not spread out quite as much as it should have been, and the hay sweep he used probably took up a certain amount of old herbage. The result was that the hayrick of fifty tons caught fire and the hay was all destroyed. There was a north-country implement that he introduced into Sussex about four years ago, which was most useful, but it had never been seen or heard of before in the south—*i.e.* the turnip-cutting cart. The cart was filled with roots and as the horse moved forward the turnips were cut into "fingers" and spread all over the pasture. In the north of England there was hardly a farm that had not got one of those cutting carts, yet they were absolutely unknown in the south, although they seemed to be just as suitable there.

Mr. James Falconer said that, as a member of the Implement Committee of the Council of the Royal Agricultural Society, he took a great interest in agricultural implements. With regard to Professor Somerville's remarks about the turnip-cutting cart not being used in the south of England, it was well known that farmers in the south were not very ready to adopt new implements; they had to be thoroughly convinced of their usefulness before they would begin to use them. The turnip-cutting cart in Scotland, and in some parts of the north of England, was very largely used to cut the turnips for sheep feeding on grass, but there were very few sheep fed on the grass in the south of England, and that was probably one reason why the turnip-cutting cart was not so much used in the south. With regard to double-furrow ploughs, he well remembered double-furrow ploughs of the Pirrie type that he had about thirty years ago, and similar ploughs were made by both Scotch and English makers. They were a totally different kind of plough from the double-furrow ploughs of the present day, and were far too heavy. The reason why the double-furrow plough was not used in Scotland to the same extent as it was in the south, where it was absolutely universal, was owing to the amount of cartage that had to be done on the farms in Scotland. It was found that, by putting the horses into three-horse teams, when the time came to cart turnips, which in

Scotland were generally pulled and stored in the autumn, the man, who had to give up his horses to make a three-horse team and go to do odd work, refused to look after them, and would have nothing to do with them when he was told to cart turnips. The consequence was that farmers in Scotland reverted to the single plough, each man with his two horses, and he thought that practice was likely to continue. He introduced the double-furrow plough into the south of England twenty years ago, because he had seen the advantage of it in the New World. In New Zealand twenty years ago he had seen the double-furrow plough worked with four horses, every man ploughing four acres in a day of about eight hours. In the New World machinery was far more largely used than in England or any other part of the Old World. When he visited France about six weeks ago he saw at one farm a man thrashing with a flail, and at another farm of 520 acres he saw a four-horse thrashing-machine of the kind used when he was a boy, and in neither case was the corn thrashed clean, a great deal of it being left in the straw. Probably the reason why English farmers were so slow in adopting up-to-date machinery was that the wages they used to pay their men were so extremely low, and they did not need to use machinery to any great extent because they could employ such a large number of men. In the New World, on the other hand, wages were very high, and the farmers, therefore, adopted machinery to a very great extent. Personally, he had been convinced of the great advantage of up-to-date implements when he was managing some sugar estates in the Sandwich Islands, the directors of the company insisting on the adoption of all the latest machines devised to save labour. When he first introduced the two-furrow plough in the south of England he was the laughing-stock of the country, but now it was in universal use, and had been a great blessing during the war owing to labour being so scarce. It was scarcity of labour that had been the means of inducing farmers to employ more machinery; they had begun to realise the advantage of it, and would do so more as time went on, because wages would be very high after the war. One implement that he heard about in the Colonies was the four-horse drill, which was still seen in some parts of England, entailing the use of three men and four horses. A neighbour of his had had one, and on one occasion they started to sow barley on the same day in two fields alongside one another, of the same size and composed of similar land, and, using one man and two horses, he had finished the work before his neighbour with three men and four horses. With regard to thrashing-machines, in Scotland almost every farmer had his own up-to-date thrashing-machine in his farm buildings, using either turbine wheels or oil engines. They thrashed a certain amount every week for the stock, thus being able to give them fresh straw, and another advantage was that everything was kept under cover. In his opinion the two-engine steam plough would never be done away with, although no doubt the tractor had come to stay; and there was a great future before electricity as applied to the driving of agricultural machinery.

Mr. W. J. Malden said the author had taken the responsible part in the competitions organised by the Royal Agricultural Society, which had done more than all other influences to further the use of agricultural machinery. With regard to the Chairman's remarks about the elevator, he thought the reason of its popularity in the south was that it was much more convenient to take the sheaves of corn on to the stack with the ordinary elevator than with a fork. Hay could be taken up quickly enough with a fork, but it could be got up rather more easily with an elevator with an oil engine attached to it. With regard to double-furrow ploughs, he had tried them on hard ground and found it very difficult to make them enter the ground at all, and he thought that was one of the reasons why they are not so popular as might be expected. Having two points to strike the ground, if one struck the ground there was another one to knock it out. On very hard ground it was all a good ploughman could do to make a single-furrow plough enter. On easy ground, however, he thought they were to be preferred for some kinds of ploughing.

Mr. Alfred Hicks wished to emphasise the remarks made at the end of the paper with regard to the standardisation of machines. The author suggested that each district should settle what type of machine it wished to adopt. In examining the price list of a leading firm he found no less than thirty-three ploughs catalogued, and he maintained that that number should be greatly reduced. If there were only six instead of thirty-three, he could obviously buy his ploughs much more cheaply and quickly. He thought that scientists in conjunction with the Agricultural Society should settle the most suitable form of machines, and not the various districts. At the present time he thought a great deal of agricultural machinery was much too heavy. He had a disc harrow which he would like to use, but it was so massive and heavy that he could not do so, and he thought scientific men ought to try to devise agricultural machines with less weight. It might be of interest if he stated a fact that probably many farmers were unaware of, that each farm horse took five acres of the farm-land to maintain it for a year. He had been very much surprised when he first read that, but had worked it out and had come to the conclusion that it took five very good acres to keep each horse.

Mr. John Allen, O.B.E., said he was principally interested in cable ploughing. At the present time there were cable ploughs working with internal-combustion engines, and he had recently seen a small set doing very good work. With regard to tractor ploughs, no doubt they had come to stay, and eventually direct traction would be used very considerably on the lighter soils, but

there were serious limitations to its use. In this country there was a great deal of heavy land which was the best for wheat-producing, but owing to the climate it was for a considerable portion of the year either too wet or too dry for tractor ploughing, and he therefore did not think direct traction would ever be successful on the heavier soils. As to the method of conveying power from the surface of the ground to the drawbar, the caterpillar method was the more practical, provided the heavy tear and wear on the chains could be overcome. The difficulty of lubricating the joints and pins under such conditions would appear hopeless. Possibly, with experience, some improved method would be devised. The direct wheel drive was much simpler. It was surprising that some makers of tractors were reducing the diameter of their wheels. His experience was that six inches in the diameter of ploughing engine wheels made all the difference in getting along on soft ground. The American tractor of to-day was a crude machine, with a very short life. Tractors of the future would require to have a longer life, but whether this could be accomplished without seriously increasing the weight was a problem. What was really required in a tractor was the highest power with the minimum weight, provided there was sufficient weight for adhesion. With regard to ploughs, he remembered that some forty-five years ago in the north of Ireland the Oliver plough was introduced, and all the farmers there that adopted it thought it a fine thing, but it gradually went out of use. In the same way he did not think English farmers would continue to use the ploughs with short mould-boards that just threw the soil over. The metal in the American mould-boards worked cleaner than the English steel. This he had proved from experience with an English-made plough, in Dakota, years ago. He was of opinion that the future of the cable plough was assured. The cable plough was at its best when pulling a cultivator, as not much more than half the power of a modern ploughing engine could be absorbed when pulling a plough, in medium soil, for the reason that the plough could not be handled if made large enough to absorb the full power. Such modern ploughing engines gave over 100 b.h.p. This power was required for handling the heavy high-speed cultivator in use to-day. The cultivator was, and always had been, the premier mechanically-propelled implement in this country. The beneficial results of cultivation were due to the high speed at which the cultivator travelled, breaking the land up in large pieces, leaving it open for the sun and air to penetrate, whilst after wet weather it dried off much more quickly. A heavy cultivator was required to run steadily and maintain equal depth. It was not uncommon for between thirty-five and fifty acres to be cultivated in a day with a large set, under favourable conditions, with a low consumption of coal. He had known over sixty acres covered in a day. The author had mentioned the economy in coal effected at the last portable engine trials of the Royal Agricultural Society, which was certainly very remarkable, but those were racing trials. He had made various tests of up-to-date compound engines in the fields, and found he could not get the horse-power for anything like the consumption of coal mentioned in the paper. If the internal-combustion engine could be stopped and re-started easily, and made more flexible, it would be more convenient than steam, but he doubted whether the actual fuel costs could be brought down to that of coal and water.

Mr. F. S. Courtney, in reply, said he quite agreed with Mr. Allen that the steam plough would plough where it would be impossible to attempt to work with a tractor. With regard to coal consumption, he did not think that with judicious firing and a good man who was used to his work the losses caused by the engine standing half its time would be so great as might appear at first sight. The coal consumption would compare favourably with that of oil in an oil engine, apart from the difficulty in the re-starting of the oil engine. With regard to the standardising of machinery, when he used the word "districts" he did not mean districts in the sense of counties, but the north of England, for instance, as opposed to the south. There were places where one kind of plough was better than another, and in those places it should be decided by the users of the machinery there, in consultation with scientific men, what kind of machines were most suitable. A plough-maker had told him recently that there were about two hundred different patterns of ploughs, but less than seventy of those were marketable things. If the number could be reduced it would be of benefit to both the manufacturer and the user. It would reduce the cost and facilitate output, and would also save an immense amount in the maintenance of spare parts.

On the proposition of the Chairman, a vote of thanks was accorded to Mr. Courtney for his interesting paper, and the meeting terminated.

OBITUARY.

Alfred Gordon Salamon.—Mr. Alfred Gordon Salamon, who died on April 9th at the age of fifty-nine, had been a member of the Royal Society of Arts since 1887. In that year he read a paper on "The Purity of Beer," for which he received the Society's silver medal, and in 1888 he gave a course of Cantor Lectures on "Yeast, its Morphology and Culture," which did a good deal to make known in this country the classical work of Hansen. He contributed a number of papers on experiments in malting to the *Transactions* of the Institute of Brewing (of which he was President in 1907), and papers to the *Journal* of the Society of Chemical Industry on the influence of phosphates in fermenting

worts, and on the manufacture of caramel. He was also interested in the manufacture of cyanides and of artificial perfumes. At one time he had a large practice as a brewers' analyst and consultant, but latterly he devoted himself more particularly to general technical chemistry, especially in its legal aspects. He was for two years chairman of the London Section of the Society of Chemical Industry, and he also took much interest in the work of the Institute of Chemistry, of which he was honorary treasurer up to the time of his death.

Edward Alan Christian.—Mr. Edward A. Christian, who had been a member of the Society since 1908, died on February 17th. He was born at Milntown, Isle of Man, in 1879, and after being educated at Christ's Hospital, he spent some years in various countries on the Continent for advanced study in electrical engineering.

In 1897 he started upon practical electrical work under Mr. Shaw, engineer and manager of the Isle of Man Tramways and Electrical Power Company. In 1903 he entered the service of the Mersey Railway, Liverpool, as rolling-stock engineer, in which position he took an active part in the inauguration of the new service, and in 1909 he was advanced to the position of assistant engineer. In 1915 he was obliged, through illness, to return home to Milntown.

He took a deep interest in social matters connected with the Mersey railway staff, being vice-president of the benevolent society and the athletic and social club.

Mr. Christian was the last male survivor of an ancient and prominent Manx family, the Christians of Milntown. They are first named there as far back as 1100, and they have held the estate of Milntown in unbroken succession from father to son since 1400. In early days the Deemstership was an hereditary office in this family, and since then rarely a generation passed without one of their members—often father and son together—filling that office, Mr. Christian's grandfather having been the last Deemster Christian.

GENERAL NOTES.

Destruction of Food by Rats.—In a letter addressed to farmers, and circulated officially, Viscount Chaplin and Lord Lambourne (formerly Lieut.-Colonel Mark Lockwood, M.P.) make an urgent appeal for the adoption of all possible means to rid rural districts of the brown rat, "an underground enemy, who destroys our food supplies almost as much as the submarine." It is pointed out that in 1908 Sir James Crichton Browne estimated the yearly damage done to food by rats, in England alone, at £15,000,000. The value of that quantity of food to-day would be nearly £40,000,000. In the rush of work on the farm, which has to be done with diminished labour, rats have multiplied. The rat will breed when four months old, and has from three to five litters in a year. Her average litter is ten, but as many as twenty-three have been found in a nest. On a moderate estimate, the English countryside is feeding one rat per head of the total population of these islands, and ten rats will, apart from what they spoil, eat a quarter of corn every year. Attention is called to the advice given in a Board of Agriculture leaflet (No. 244).

Cannel Coal.—The Ministry of Munitions has been asked in the House of Commons to state how many modified plants for the distillation of petroleum from cannel coal are now in operation at gasworks in Great Britain, and what production has been obtained up to the present. The Parliamentary Secretary to the Department, while declining on public grounds to give details of production, said that gasworks in Great Britain are either now modified, or in course of modification, to enable all the cannel coal which is known to be available to be carbonised for the production of oil. He added that the process so far has been an unqualified success, and that the results were even better than were expected.

Water-power in Spain.—In the Spanish Senate on May 3rd Señor Cambo said that the Government is occupied with a large scheme for the development of hydro-electrical energy, and he more than hinted at the existence of a plan for working thus the main railways of the country. According to the special correspondent of the *Daily Mail* in Madrid, practically all hydro-electrical plant in Spain is run with machinery supplied by Germans whose "usual commercial forethought has been displayed in a systematic cultivation of the subject as well as in a good deal of surveying and buying of properties where this power could be developed on a large scale." There is said to be enough water-power in Spain "to do the whole work of the country." The correspondent points out that the industrial development of Spain is "hung up for lack of communications and transport," the latter at present depending on coal.

Indian Hides for Canada.—According to information laid before the Imperial Institute Committee for Canada at a recent meeting in London, under the chairmanship of Sir George Perley, High Commissioner for Canada, great interest is being taken by Canadian tanners in the representative collection of Indian cowhides which was despatched to the Dominion by the Hides and Tanning Materials Committee of the Imperial Institute. The collection is being exhibited at various centres under the auspices of the Canadian Ministry of Trade and Commerce, and several inquiries have already been received from Canadian firms as to supplies of the hides. It is probable that as soon as the Government restrictions on the disposal of Indian hides are relaxed, a considerable trade will be done direct with India.

NOTICE.

NEXT WEEK.

WEDNESDAY, MAY 29th, at 4.30 p.m. (Ordinary Meeting.) MARTIN O. FORSTER, D.Sc., F.R.S., Treasurer of the Chemical Society, and a Director of British Dyes, Ltd., "Organic Chemistry in Relation to Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 24th, 1918; The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Brown, Joseph Pearce, J.P., Plymouth.

Kingsford, William Edward, Cairo, Egypt.

McConnel, John Wanklyn, M.A., Manchester.

Ramsay, Alexander, Lincoln.

The following candidates were balloted for and duly elected Fellows of the Society:—

Barrett, Frank, Grimsby.

Campbell, Oliver Hering, London.

Chopra, Igbal Chand, India.

Cobbett, Colonel George Talbot Burrows, London.

Cockill, Harry, Southport.

Davies, Frederick Herbert, London.

Dickie, James, Ayr.

Dobson, D. Bennett, Thames Ditton.

Feltoe, Rev. Charles Lett, D.D., Dover.

FitzGerald, Francis William, London.

Forbes-Bentley, Lieutenant Rupert, R.N., Beckley.

Harrison, Joseph, Hon.A.R.C.A. (Lond.), Nottingham.

Hugh, James, Bothwell, Scotland.

Ishii, Shinji, London.

Lathe, Alfred, Bilston.

Nisbett, G. H., M.I.E.E., Liverpool.

Reddan, William Holmes, Mansfield.

Singer, Edgar Ratcliffe, Frome.

Statham, Noel, New York City, U.S.A.

Tuck, G. O. Kentucky, U.S.A.

Underwood, Oliver, London.

Watson, Charles Edward, Wall, North Tyne.

The paper read was—

THE MENTAL EFFECTS OF THE WAR AND THEIR LESSONS IN REGARD TO MEDICAL AND SOCIAL RECONSTRUCTION.

By MAJOR SIR ROBERT ARMSTRONG-JONES, M.D., R.A.M.C.

It has been truly said that the most eventful as well as the most interesting period of a nation's psychology is that during which its people is passing through the crisis of war, and in his search for a moral equivalent for war, William James, speaking as a psychologist, stated that the martial type of character might be bred without war. He expressed his belief that the military temper might find a substitute in an imperative and obligatory service to the State, and he remarked that some professions, in particular those of the priest and of the medical man, were in a fashion educated towards this type; for they were taught to show strenuous honour and to practise disinterestedness in the war against disease, poverty, and sin; but in an imperfect world we know that the military temper and the martial spirit are means to an end, and they are bound to be some

of the means by which the ideals of self-sacrifice, social justice, liberty, and human brotherhood may be defended. Grotius has said "War is waged for the sake of peace," and it would show a shrinking from responsibility and a craven spirit if these ideals should pass undefended because of the suffering involved, or the carnage inflicted, or because of the risk of loss of possessions or of treasured achievements which war might bring about. We have entered upon this war for ideals, and we hope not to sheathe the sword until these have been secured for the weaker nations struggling to be free.

The war has now lasted over three and a half years, and is without any immediate prospect of cessation. It has disturbed the mind and altered the course of thought of whole continents, and out of the great cataclysm of human struggle it is fervently wished that a better world may emerge. It is within the scope of this Society, founded in 1754, to consider any prominent subject dealing with the life or the health of the people, with its social habits, as well as with the production and organisation of its commerce, and any scheme of "reconstruction" after the war must find an encouragement in the support of the Royal Society of Arts.

As this paper purports to deal with the mental effects of the war in their wider application, it may be pardonable if it is remarked that in normal health the mind acts as a whole; the action of the nervous system being described as of the syndromic variety; but under abnormal, or unusual conditions, the effect of any great psychological stimulus is to create a dissociation of the mind as a unity and to cause its various elements to become severed or disconnected, so that self-control and inhibition, for instance, which are characteristics of the higher man, tend to become impaired or even to disappear, the emotions to become intensified, and the will to lose its domination so that actions become impulsive and irrational. The great lesson of the war has been to show that man, in his mental build, is a co-ordination of many primitive instincts, feelings, and actions, which have gradually been built up and correlated for the benefit of the whole. In the primitive amœba, such as paramœcium, we find that, although each cilium contracts independently, they are all co-ordinated to act in a very definite and rapid sequence so as to produce the movement of the whole animal, yet the effect of certain reagents applied to the cilia is to bring about irregular and dissociated contractions. The same results may be seen in the contractile umbrella of the jelly-fish, for although each group of nerve cells controls a particular area of the umbrella, they are all so well co-ordinated normally that the bell contracts as a whole and with a proper rhythm. Precisely the same analogy pertains to human beings: the mind normally acts as a whole and in a unified scheme for the benefit of each individual, just as individuals unite together in a well-ordered social group for the common good; but when any inordinate stimulus is experienced by the group or by any of its constituent parts the tendency is towards a dissociation or to a want of balance of the whole. In certain individuals the effect of the war has been to produce a dissociation of some of the elementary constituents of the mind, and these have either over-acted in the presence of others or they have been suppressed. It is a fact of experience that during this war a special strain upon the mind through the over-action of one element has brought about a disintegration of the whole; and it follows from this dissociation—and it is helpful in securing restoration—that any factor which contributes to the welfare or to the improvement of one element also contributes to the improvement of the whole mind.

War-shock or shell-shock has demonstrated fully the dissociative effects of a great emotional strain upon the mind, and, secondarily, upon conduct, and this has occurred in many thousands of instances. This mental abnormality is in all probability the result of the emotion of *fear*, which man has experienced and recognised from the earliest stage of his evolution, and it is one which he has tried most to avoid and to control, lest it should seize his whole personality. The fear of solitude, of being without protection, of vast distances, of open places, of closed spaces or of great heights, and of darkness, are notable instances of this occurrence of the emotion of fear, which may be revived under stress or through unusual conditions. One of the most common manifestations of this feeling of fear in our sick soldiers has been muscular trembling and a motor inco-ordination varying from very mild shakiness to general convulsive seizures bordering upon epilepsy, and which, in so many instances, has been most difficult to relieve. It is without doubt that fear is the most powerful stimulus that can be applied to effect a muscular discharge, for the purposive end of fear is to cause flight and to ensure safety; but in the combat of war the duty of the soldier is to stand his ground and to defend himself and his country against aggression and

attack. It is only when the natural and instinctive feeling of fear unconsciously collides with the higher developed duty of the citizen that a conflict occurs; an intense effort is made by the higher centres to suppress this primitive fear; after a long struggle the effort at suppression fails, and shell-shock results. Should the victim of this mental conflict be wounded the wound provides a more ready diversion for his thoughts and an easier channel of outlet for his pent-up emotion, and he rarely then becomes the subject of mental dissociation. It must not be assumed that shell-shock cases are wanting in courage. They are often the most sensitive and brave and adventurous. Cases are known among the most seasoned soldiers of the old Army and even in a V.C. For his restoration it has been found by experience that new interests and a cheerful confidence amidst natural surroundings provide the best means to recovery, and, fortunately, if only the lead is given, there are many persons in civil life both willing and ready to offer this necessary help, which may, perhaps, best be described as a cure by the "return to the land."

The psychology of the war has brought us into contact with life in a manner that no national upheaval has ever done before, and the emotions have been kindled in a way never previously experienced. There has been among the civil population an excitement or a mental erethism that has caused the emotion of disgust or anger to be most unreservedly expressed. Especially is this the case in regard to the barbarous and inhuman cruelties imposed by the Huns upon the vanquished: women have been outraged and children murdered and mutilated. The soil of Belgium has been drenched with the blood of martyred hostages, and we ourselves know what has occurred to the devoted Nurse Cavell, to Captain Fryatt, to the "Lusitania" and to our hospital ships; the emotions of horror and disgust have been loudly expressed over these revolting cruelties, but hope and the tender emotions have not been omitted; the love of home, of patriotism, and the feeling of pride in our race have been kindled and the world of idealism has been roused to a degree never before witnessed. The war has certainly brought the emotions into greater and clearer relief and has given us all a much wider psychic experience, and one experience within the range of everyone is that "privilege" during the war has been vastly curtailed and "equality" rules in social conditions, for every person in the kingdom is, or soon will be, in the same position with respect to his daily food; the richest man in the richest city is no longer able to indulge his desires. He cannot choose what he will have for dinner; owing to the acute disturbance to domestic labour he cannot enjoy the services he formerly commanded; he is unable to travel except by motor-bus or underground, for a taxi may not be available; and he is unable to meet his friends, for his friends cannot entertain him, or they are engaged in doing work of national importance. This state of things is bound to leave a permanent memory and to mould the character of the young and to show them one great lesson, which is the need to work and the continuous necessity there is to be careful and sparing in the national interests.

The changes that have already taken place in the habits and social tendencies of the people are enormous. In the absence of an overwhelming sorrow and anxiety everyone now talks of rations; and of all interests, probably housekeeping is the most absorbing; the eternal topic is household management. Cooking receipts, house-cleaning, and dressmaking command more interest now than ever before, and who will say that these are not of distinct benefit to the country, for in consequence there is less waste of food and more variety, and it is more carefully prepared. As a housekeeper says, a pennyworth of rice has to go farther to-day than a sirloin of beef went before the war, and every home in the land is better for the lessons thus compulsorily taught in domestic economy. Most young women and many wives and mothers are to-day offering their whole strength to the nation, and their great aim when they return home is to learn how far their food will go, how they may dress without extravagance, and how the home can be kept clean with fewer servants. Thrift has also received a marked encouragement. Before the war little or no interest was taken by mothers or by children in the savings banks, as "it wasn't worth while." Now, most families are capitalists owning war certificates, and the use and value of saving small sums has been realised by every person. In every town and village, even in the large cities, the men, women, and children are awake to the fact that scarcity of food may merge into famine, and they have been busy during the seasonable months of the year in cultivating allotments; making the utmost use of every acre of fertile land, taking an interest in production, and talking about their gardens. More is known to-day by the masses of the people about the varieties of

potatoes and the best kinds of cabbages and onions for food than was ever known before, and instead of idle loafing and consequent discontent, the engrossing interest in their leisure has been over their crops or the care of their plots—not only to the great benefit of their bodily health, but also to the happiness and contentment of their homes. Barrows in the streets now provide seeds to sell for garden vegetables, and they are only supplying a demand created by present social conditions. It is not improbable that the "land" may completely solve the problem of undue attention given before the war to athleticism both by men and women, and it is not improbable either that the "land" may be the great solution of some of the problems confronting women after the war. It is estimated that there are twenty-five millions of men and women in this country, and each of them is encouraged to continue cultivating the land and doing his or her share. If a small plot of even one-tenth of an acre per person were used for potatoes, for example, it would give us two and a half million acres, which would be five times more than was grown last year, and in this way we should be helping to solve the shortage of food for at least another year.

It has been suggested by an eminent thinker and philosopher that what is required in social reconstruction is not only more material goods, but more freedom, more self-direction, more outlet for creativeness, more opportunity for the joy of life, more voluntary co-operation and less involuntary subservience to purposes not their own, and to obtain this he is ready for the destruction of institutions or of the established order of things in so far as they are hostile to the higher instincts and to the individual impulses of men and women; but the individual impulses of men and women are unreliable factors in true progress, although it must be admitted that both our individual and social life are dependent upon impulses and instincts whose nature and origin are primitive, but these have become modified through long periods of evolutionary development and through the influence of civilisation they have developed into highly organised and complex tendencies. It is these tendencies, and not the original instincts, that must be considered when dealing with the basis of reconstruction. Society, owing to the war, is in a state of flux, and we see the inadequacy of present arrangements in many departments. We need not only great wisdom, but also the will to act, for reconstruction is no longer a matter for philosophical speculation. An ineffectual yearning is a mere dreaming, and we need not only the will but also the courage to act. At the same time I am quite prepared to admit that our present vision of affairs is a partial one, because we have yet to know exactly how the war may end or whether the masses of the people will tolerate in peace time the restrictions imposed by the war. There may be a great rebound, and a great reaction may be in store for us after the war, associated with all kinds of mental, moral, and bodily excesses and indulgences, so that, in spite of the grave anxieties we have experienced, the war period may be contrasted with it even as a happy one.

We can all say that we have already watched the general trend of social movements, and we need to take to heart seriously and deliberately the lessons taught to us and to prepare ourselves for the legislation which is inevitable, and which many thoughtful people may even consider to be revolutionary.

I venture to think that there is one lesson taught by the war which will be of doubtful advantage—viz., that in the hurry and haste of war-work everyone has become more abrupt and less regardful of the amenities which were formerly considered to be the "salt of the earth," both in public and in private life. There is to-day less consideration for the ceremonies, conventions, and courtesies of social existence; but this is only a continuation of the feeling which began to make itself evident towards the close of the Victorian Era, and which has had the wholesome effect of extinguishing the "Cranfordian" tendencies that were both superficial and insincere. The question, to my mind, is whether the war has not caused a swing of the pendulum too far, and whether we shall not miss the kind word, the gracious act, and the considerate conduct which marked the dealings of men and women in pre-war days.

Church.

The mental effects of the war upon religious feeling in the country have been discussed in the lay press, as well as in Church circles, and the matter has been the subject of pulpit addresses; but up to the present there have been no marked religious developments in consequence of the war; in fact, it has not had the effect expected, viz., to remove the spirit of indifference which prevailed both among men and women before the war. A new atmosphere of purpose has certainly been

created by the war, but it cannot be said to have extended into the Church, although some few distinguished clergy have urged members to strike for freedom and to attempt to rebuild the national life in the spirit of liberty, justice, and enterprise.

There has been a desire on the part of some of those who minister to the spiritual welfare of the people, to see how the men themselves lived in the front trenches, and some few have taken combatant rank and have sacrificed their lives in the defence of their country's honour. The feeling kindled by common service and by common suffering in the trenches, and the experience gained in hospitals and homes, ought not to be without good results. It should become the basis of unity and good fellowship between different classes of men and between different grades of society, and it should supply the opportunity for urging a new spirit of sacrifice and citizenship in the days to come; but the stern discipline of war has so far not led men and women to turn their thoughts and minds to things spiritual, nor has the Church—which in the past has provided out of 20,000 schools about 12,000 in which secular teaching was combined with the teaching of religion—given since the war any special attention to the encouragement in the young of a law-abiding citizenship, which, in view of the great increase in juvenile delinquency, is a serious need. True, there have been the usual confirmation classes and Sunday schools, but little beyond these. It has been very different in America, where far greater efforts have been made, since the war, to increase the sense of fellowship; but we realise there must be in America a greater need for assimilating the influence of foreign immigrants.

The teaching of the Church is broad enough to include two aspects of social endeavour that may justify their consideration by this Society; one is the great question of intemperance, which was the greatest curse until it was strongly taken in hand by the Central Control Board (Liquor Traffic), and the other is the social disease whose ravages are so well known to the Chairman, and which have been so freely ventilated in the medical and lay press, and through the National Society for Combating Venereal Disease. These are two great and dark shadows that stand across the field of reconstruction, and the latter is now being taken up by the Army authorities. It should also be approached by the National Church, and could probably be most successfully overcome by the personal relationship between the clergy and the people.

The future prospects of the country depend upon the ideals that are implanted upon the rising generation by the various schools of thought represented among the clergy of all denominations. It would be the irony of an evil fate if the ideals we have fought for, and sacrificed so much blood and treasure to preserve, should fail to bring us spiritual comfort, unity and strength. The creation of new industries to replace those of war, and the preparation of the body and mind for the future reconstruction; the disintegrating cupidity associated with competition, and the social bitterness which is inevitable, are all conditions which the teaching of the Church should be brought to deal with; but the Church, as a whole, has held aloof from them up to the present. In a collection of essays by seventeen chaplains from the front, the general opinion is confirmed that the war has not brought a "revival of religion" as understood at home; but the war has created a mental effect which may best be described as self-surrender to a cause and self-subordination to the interests of a common purpose; and life since the war has certainly appeared to be of some purpose, even to the most careless and profane and apparently irresponsible. To these it has brought a sense of vocation and a feeling of common loyalty which must be recognised. The soldier believes his cause is right, and that it is his duty to see right triumphing over wrong, and he has come forward with others in a spirit of brotherhood to show his faith. Speaking psychologically, there is no possible doubt but that fellowship has been a reality at the front; it has existed between laymen and clergy, as also at the front between ministers of the various Christian Churches. Whether the lesson can be taken to heart and a great spiritual objective presented, bound by a common membership pledged to a common loyalty for a common end, remains to be seen. We find many different claims are being put forward, such as that for a more extensive modification of the Prayer Book, or for a more modernised catechism, or for more freedom to realise self-fulfilment and to enjoy a fuller and stronger social life, and it is certain that these are healthy signs, for they are put forward by thoughtful men with the single aim of spiritual betterment. The Archbishops of the two provinces have realised the need for more workers to direct the lives of those who are to replace the flower of our people, whose

graves have hallowed the soil on the various battle fronts; whilst others see the pressing need for spiritual influences to modify dangers from within as well as to avoid the bitterness of social unrest. It is for this reason appropriate that the work of the Church should be brought before this Society, which has always tended to improve the lives of the people, on the mental as well as on the physical side, by cultivating an appreciation for the arts, for science, and for a good literature to be placed before them. I need not say anything further to justify my placing the work of the Church in any scheme for social reconstruction.

Temperance.

One of the most striking lessons of the war has been in the direction of temperance reform, and this is a very crucial as well as a much-debated topic. It may be remembered that so serious had matters become six months after the commencement of hostilities, through drunkenness, impairment of health, loss of workmen's time, and general bad temper where a large population had congregated for munitions and other Government work, that the present Prime Minister described "the drink" as a worse enemy than the submarine, and in consequence the Liquor Traffic Control Board was instituted by Parliament in June, 1915, under the Defence of the Realm Act, with Lord d'Abernon as its chairman. He gave the matter his full attention, and he deliberately considered drinking continuously or at very frequent intervals, especially during working hours, to be at the root of the evil, and to be the proximate cause of most of the physical and mental disabilities among workers. The Board set out with a definite policy, which, speaking generally, was to stop continuous drinking and to discourage all drinking except at meal times. The results of the work carried out by the Board read like a romance, and it is only short of marvellous that the Regulations of the Board, which have the validity of an Act of Parliament, should to-day be controlling the lives and habits of 38 millions of people out of the total 40 millions which constitute the population of Great Britain, and all this without explicit Parliamentary sanction; but it must be noted that the Board has not acted in a single instance without an application to do so being presented by the local naval, military, munition or transport authority. Wherever the Board has exercised its powers, there the convictions for drunkenness have diminished by one half—from 159,000 convictions in London and forty large towns before the war to 77,000 in 1916 and to 45,000 in 1917. The streets have become more decorous, the station platforms more orderly, the people more tranquil, and crowds less excitable; the workers have been healthier and their minds less irritable; there has been more contentment among the mass of the people; they are more reasonable, and they have got through more work. These specific attainments of the Board have been testified to by chief constables, who record a diminution of drunkenness and disorderly conduct in England and Wales from 2,688 convictions a week in 1914 to 850 in 1917, also by medical officers of health, and by social workers; district nurses have similarly spoken, and even members of the licensing trade itself have expressed approval. This is a war-time measure only, yet its achievements and their lessons have left an indelible impression upon the country. No scheme of reconstruction can disregard the success which has attended the thoughtful and successful control of the Board over the drink traffic, for not only has the Board restricted the sale of alcoholic drinks, but it has also provided counter-attractions to the ordinary public-house business by recreation and entertainments, and it has also arranged postal and banking facilities for their customers. Before the Board was instituted, the former policy of regulation and restriction under private ownership had already received a full and fair trial; it had reached its effective limits and was found wanting. Thoughtful people are not likely to let the work of the Board be forgotten, it has meant so much to women and mothers and homes, and the women who have benefited will now, with the extended franchise, help to control the drink problems, and there must be no competition or quarrel or jealousies between temperance reformers about ideals which will only result in destroying what, by an overwhelming consensus of public opinion, has been the great lesson of the war.

Whether we should continue the limitation of output and what can be done to prevent the loss of revenue, or whether there should be State Purchase are questions of practical statesmanship in regard to which Lord d'Abernon must be the best authority.

The period of demobilisation may not be far distant, and, as has been wisely said, "Scenes of drunkenness will be a dishonour to a nation that has been fighting for right and righteousness." Our men will be returning home after most strenuous times, and there is bound to be some reaction. Those who have faced dangers,

and exposed their lives to so many risks for their King and Country, will feel that they are entitled to more ease and more material comforts than in the past, and the question of dealing with drink must be the first consideration. After the war there will be many social difficulties —many of these have probably been foreseen— but there may be destitution, shortage of food and money, and perhaps of employment confronting us; but one of the chief lessons has been the outstanding example of what has been done in regard to sobriety, and to ensure orderly conduct among the masses of the people, by Lord d'Abernon and his Board during the stress of war.

It remains to be seen how far, if at all, the country will ever wish to return to the periods of wild orgies, violence, and panics associated with intemperance, or whether there will be a response to the efforts made now to receive back our soldiers into a purer and more ennobling world. The young men of 1940, for instance, will depend upon what is done now for their mental equipment and physical vigour to enable them to compete successfully in the periods after the war.

CHILD LIFE.

Next in importance to the marvellous changes brought about in the habits of the people consequent upon the war, has been the fuller realisation of the pressing importance and the sacredness of child life, and the lesson taught is the precious care that should be exercised in its protection and supervision.

To most persons the war has been a great convulsive shock; but to parents it has brought measureless disasters, and to the State it has revealed at this crisis the supreme value of man-power, and the consequent duty imposed on the nation to care for the young. A declining birth-rate is a loss in power and prestige, and the loss of every potential citizen is a loss in creative power and in earning capacity. The birth-rate has been gradually falling ever since 1876, when it was 36·3 per 1,000, until it reached 22·0 per 1,000 in 1915—the lowest rate yet recorded, and a great loss to the country. Add to this the loss of life caused by the war, which implies not only a direct economical shortage but also an indirect injury, because the family has been deprived of its ruling and directing authority as well as its protecting and earning head. It is estimated that at least 100,000 children will be left fatherless owing to the war, and the orphans must be cared for as the Minister of Pensions has recently insisted. The orphans of our soldiers must be guarded against hunger, destitution and disease, because these are conditions which lower mental vigour as much as they impair bodily efficiency, and they tend to lessen the output of work of those upon whom in the future the country must depend for its proper place among the nations.

The loss of male life through the war has created the necessity for the employment in various capacities, and on a large scale, of many married women, and it has become a matter of supreme national urgency that the children should be cared for whilst their mothers are at work. Although we already have a large number of institutions of various kinds, *e.g.* small observation wards for slightly ailing babies, small lying-in homes for poor mothers, dental clinics for mothers and the children that are under school age, yet it is not generally realised that over 100,000 babies die every year in the United Kingdom; that out of 1,000 babies, 250 die either during the first year or during the ante-natal period. It seems an almost incredible revelation that out of 1,000 infants born, eleven die within the first hour, twenty-two within the first twenty-four hours, and thirty-six within the first month. These figures show the appalling loss of infant life that is occurring every day, and they call loudly for preventive measures for their arrest, and which the Maternity and Child Welfare Bill recently presented to Parliament is destined to avert as a prodigious national loss, especially if it can be made compulsory.

The lessons we have learnt during the war show that mothers must receive practical instruction in the care of young children, as also in the making of their clothes, in preparing food and drink for the sick, and in domestic cleanliness and home nursing. Mothers should receive, by State control, proper, prompt and skilled attendance before, during, and after confinement; infants should receive treatment until the child goes on to the school register, and the home should be visited by authorised persons so as to foster a public opinion educated to set a high value upon infant life, and not to tolerate its neglect. The rebuilding of our manhood is only possible when the dignity of motherhood has become the corner-stone of our public faith and creed.

The war has immensely stimulated people into a common purpose about children, and nothing has done more to concentrate national attention upon the ignorance, carelessness, and neglect in connection with child life, and the

permanent damage to mother and children that is still going on than the realisation of the enormous sacrifice of our adult manhood in this war. Not only is the Government, but also many local authorities are now awakening to the great interests involved in saving children by the help of health visitors, and by the establishment of infant welfare and maternity centres, crèches, day nurseries and schools for mothers, which the new Bill and the Education Bill propose. Nor is this solicitude confined to public bodies, because large employers of labour for whom women work in great numbers (*e.g.* Anderson Scott and Sons, of Carlisle, and others), have made arrangements for special rooms with plenty of light and sunshine to be used in their works as nurseries with qualified women in charge. So much are these facilities appreciated by the mothers, that they willingly pay small sums—from 5*d.* for one child to 8*d.* for two—to cover the cost of the food supplied to their children, whom they are able to visit at intervals during their working hours. There have been more infant welfare centres and day nurseries started since the war than during the previous ten years, and although there had often been health weeks before the war, there had never previously been a Baby Week, and fortunately welfare work has never been the bone of contention of party politics. In July, 1914, there were 400 infant welfare centres at work, but happily since the war these have increased rapidly, and now there are 1,200 at work, and their numbers are still increasing, and it is satisfactory to learn that although 5,000 of these are necessary to compete adequately with the work, the growth of these centres is both rapid and regular. There are to-day no less than ninety national or central societies at work, doing practical organisation and effecting propaganda about the treatment of babies, and there is a growing need for the co-ordination of educational societies rather than for their further competition in practical action; and we hope this concentration of efforts may come when the Minister of Health has been appointed. Although, so far, we have made few sacrifices compared to those made by the soldiers at the front, we have made some progress in matters pertaining to health, but unless some scheme of reconstruction is actually commenced during the war—and the Notification of Births (Extension) Act, 1915, affords a most helpful basis—there is a fear that the incubus of lethargy and indifference may again re-assert itself.

The National Association for the Prevention of Infant Mortality and the National Society of Day Nurseries, have worked hard in order to keep the children of working mothers properly fed, clean and looked after whilst they themselves were at work. The National Union of Women Workers has long since advocated the establishment of nursery schools with small clinics attached where the mothers, when present, may be taught to sew and to cook, and where the babies may benefit through medical consultations, especially in case of wasting or malnutrition, and the National Union has initiated a number of these baby hostels in different centres; a feature of some of these being the supply of milk for the infants to supplement breast-feeding, or where this is impossible. Some town councils have most creditably helped in this matter, and a great deal of useful work is done by training so-called "home helps" to look after the babies, but voluntary effort cannot be relied upon to yield either the necessary financial support or to carry out the work without proper remuneration. The work of these societies is arduous and continuous, for they endeavour to restore the deficiencies consequent upon a faulty home life, and re-education is needed which takes time and trouble. Many local authorities have already appointed tuberculosis officers—as they are called—to examine and advise in regard to children who have been damaged or maimed by tubercle, and it is not realised how destructive this is to child life. From 1914 to 1916 inclusive, 71,007 cases of non-pulmonary tuberculosis were notified, of which no less than 25,451 died under the age of fifteen years. These figures show how prevalent tuberculosis is in young people, and yet it is a condition which is eminently remediable in the early stages. If places may be named, Huddersfield in particular has taken the matter of child life into its serious consideration, for 97 per cent. of the total births in this city are visited by medical officers immediately upon the receipt of notification of birth. York is also showing much activity in this direction, and Leeds in 1916 established by voluntary effort a home for the children of soldiers and sailors during active service, which has now passed under municipal control, for the Sanitary Committee of the City Council has taken over the work, which is now undertaken by a joint Infant Welfare Committee from nine centres, and composed of members of the Sanitary Committee and the Leeds Babies Welcome Association, with the result that the relief afforded is worked as a hospital under the

direction of the Medical Officer of Health and his assistant, in conjunction with six trained nurses and eight probationers, and this hospital gives advice as well as treatment for the three great disabling illnesses in children, viz., rickets, marasmus, and tuberculosis. Bournemouth also has its Health and Mothers' Aid Association.

In regard to ante-natal care, which means the control of causes contributing to many of the child fatalities that occur during confinement—and during the nine months of ante-natal existence it is computed that 100,000 infants are miscarried annually, or are prematurely or dead-born—the Midwives' Institute, among others, has issued special instructions to midwives, urging them to aim at saving life by keeping the pregnant woman in good health, bodily and mentally, so as to anticipate any complications at this period by securing appropriate treatment in time, and thus preserve pregnancy to full term. The midwives are well able to advise as to the toxæmias of pregnancy, the havoc of venereal diseases, the adequacy of pelvic measurements, and some of the dangers to be avoided by being able to test and examine the urine. They are particularly advised to visit the home "by consent," and give help as to the personal care and arrangements desirable in the interests of the mother and infant. It has been suggested by some, and already an effort has been made, to standardise the qualifications for welfare workers, because it is found that women of widely different attainments hold similar posts, some of them having only a comparatively short experience, whilst others had given years of arduous service in a hospital or an infirmary, and had in consequence developed fully their capacity for responsibility. The need for such a standard for Women Sanitary Inspectors has already been brought to the notice of the Local Government Board, which has recognised certificates for Health Visitors granted by various training centres, the duty of these visitors being to keep children that are over a year old under supervision, so as to prevent rickets and the special respiratory diseases to which they are so liable. The great Association of Infant Welfare and Maternity Centre is endeavouring to extend its affiliated branches, and it has started an Employment Information Bureau, but there is a pressing need for superintendents of maternity and child welfare centres, because so many mothers are ignorant of what is now very significantly called "mothercraft," and they are too apt to give up breast-feeding for some advertised fashionable food which perpetuates a lack of vigour and a lessened resistance to disease in the child. The work now being done by the National Association for the Prevention of Infant Mortality, by the Women Sanitary Inspectors and Health Visitors Association, by the Local Government Officers Association (which, as far back as 1905, formed a central organisation with local guilds), and also by the National Union of Women Workers of Great Britain and Ireland, with its 2,000 women enrolled in the Patrol Committee: all these show the need there is for workers in relation to health and the still greater need there is for co-ordinating organisation by a Minister of Health, who would already have at his service not only the efficient help of the Local Government Board, but also the most valuable help of the National Insurance Commission, through its Medical Research Committee. In America there has been great progress in the direction of supervising officially the various social conditions which affect child life; an official has been appointed who is described as the Chief of the Children's Bureau, and he is attached to the U.S. Department of Labour. His duties are to collect such facts as the influence of the density of the population upon child life, to report upon the types of recreation facilities which should be available in any one city, and to give information as to school buildings, playgrounds, open spaces and play retreats for small children, so as to prevent street play and loitering, which are forbidden by law. The work of Sir Arthur Newsholme, Mrs. Humphry Ward, and others, has well prepared the way for special action upon this aspect to be taken in this country.

Whilst upon the subject of child-life, the war has taught us to reconstruct our attitude towards "illegitimacy." In a recent address Sir Bernard Mallet has shown that, in spite of unfounded alarm and rumours, there is a practical constancy in the number of children—about 50,000—who are born out of wedlock annually in the United Kingdom, of which over 36,000 are in England and Wales. There is a much heavier death-rate among this class of children than among the ordinary; the infant mortality is two or three times greater in those born out of wedlock than is the case in the legitimate offspring, and this fact is true both in this country and in the Colonies. In the Borough of Hampstead, which has many social advantages, the child mortality, in or out of wedlock, is as 197 to 60, and in New South Wales it is 162 to 67, and the reasons for this are want

and necessity. If there is no parental responsibility and no protection, the lot of the necessitous mother is hard, and this is the chief cause of the high mortality among the illegitimate; for if, as in Norway since 1914, the State assumes the father's responsibility, or finds him and fixes the care of the child upon him, the death-rate among illegitimate children falls to the normal rate. This fact shows incontrovertibly that infant mortality is tried by and governed by poverty, want, and anxiety. Remove these and the children live. There are not a few persons who feel that any relaxation of deterrent measures may become a moral danger, but the question must be viewed primarily from the public health standpoint, and the interest of the child should be considered paramount. Upon this reasoning there should be no differential treatment shown towards any necessitous mother, and public feeling since the war tends strongly to this view, and it is advocated that there should be special waiting homes for expectant mothers, and also some place where mothers could remain with their children for a time, or at any rate during the period of nursing, and that they should be provided with a suitable allowance to enable them to help to pay for the use of special day nurseries. There may rightly be differences of opinion as to these homes being rate-aided or self-supporting, but a strong feeling exists that the assistance to unmarried mothers should not be through the Poor Law. It is certain, however, that the law must be altered so as to enable adoption to be safeguarded and legitimation of the child to be secured by the subsequent marriage of the father and mother, and possibly in other directions which will be indicated when referring to the lessons of the war upon the law. It is permissible to infer that in regard to child-life, the war has "created an atmosphere" in regard to the falling birth-rate, also in regard to infant as well as to maternal mortality, and to the damage to both, which can be avoided; that the work of the midwife, the health visitor, the district and school nurse must be better known and more fully appreciated, and that local authorities must obtain further increased power, by the legal sanction proposed, in order to support maternity centres, infant welfare organisations, and hospitals in particular, so that the different local authorities may be enabled to deal with these two very important factors of mother and child. All of us are aware that the Local Education Authorities and the Local Government Board have already used their present powers to supply grants in aid of maintaining the work of accredited institutions, but this needs extension and co-ordination, and although I cordially appreciate the work of voluntary committees, there is far too much of this left to the humanity and generosity of the public, and we must remember that the voluntary work of one generation becomes the accepted duty of the State in the next, and this is one of the lessons of the war.

Another of the great lessons of the war derived from the increase of juvenile crime has been to direct greater attention to attracting the children by amusements so as to provide them with diversions from the streets, and to promote the welfare of boys and girls by offering them useful counter-attractions to loafing and the temptations to be idle. It is necessary that all educational authorities should be in touch with what is being done voluntarily in this way by each authority in its own district, and the first Education Bill proposed a special standing committee, called the Juvenile Organisations Committee, for the purpose of supporting the work carried on by voluntary organisation amongst boys and girls who have left school. Lord Desborough pointed out the value of this in a strong appeal for a closer connection between all the societies working in the interests of the juvenile adult, viz., those between the ages of fourteen and eighteen; and I venture to suggest a further link which might be of the utmost help and value, that all school children during their last year of school life should be brought into touch with the voluntary clubs in their district. The fact that representatives of the Federation of London Working Boys' Clubs were to be on the Juvenile Organisations Committee was a great hope for London, as the children of to-day will be the rulers thirty years' hence, and the good and wholesome influences of these clubs will prove to be an inestimable asset to the country when the boys grow into men.

MEDICAL.

In the department of medicine we have received far-reaching lessons, and the chief is the value to surgery and medicine of the ancillary departments of bacteriology and microscopy. These are in future destined to be the indispensable assistants of the physician and surgeon, and their interpretation of the condition of wounds has been invaluable, as no surgeon will in future operate upon deep and broad areas of wounded surfaces unless he has the assurance of the bacteriologist and microscopist that the procedure is free from risks. Probably there

are at least five principal lessons derived from the war in regard to surgical practice which are bound to afford considerable benefits and advantages in the future to the civil population. One of these, which had been adumbrated before the war, is the success attending the transplantation of bone, or the surgical method described as bone-grafting for serious injuries and diseases, and experience has shown the value in this regard of "fixing" all bone injuries. Closely related to this is the importance, and even the necessity now agreed upon by all the great surgeons, of retaining —except in "stumps"—all loose pieces of bone or "sequestra" in comminuted fractures—*i.e.* so long as these pieces of bone have the slightest tag of periosteum attached to them, and sometimes even when they are free. A third lesson derived from the war has been the great success attending the so-called excision of wounds. All gunshot wounds may correctly be described as septic; hence the great discovery of the value of excision of wounds, and there have been few wounds throughout the war which could have been treated upon aseptic lines, and, in consequence, the method has been antiseptic rather than aseptic. As a corollary from this has been the supreme value of intermittent application of an antiseptic in the form of hypochlorite of sodium, in order to cleanse wounds and to destroy bacterial infection. This treatment of wounds by periodic irrigation or suffusion has been a great discovery, and is attributed to the genius of two men whose names it bears—viz., the Carrel-Dakin treatment of wounds. It enables extensive septic surfaces to be cleansed and to be subsequently drawn together by primary or secondary suturing, when union and healing take place directly. Although this surgical treatment has been one of the most important discoveries, it is only right to state that there are some surgeons of eminence who consider that it has risks of its own, one of these being secondary hæmorrhage, the bane of surgery in the remote past. Fourthly may be mentioned the advance in the surgery of the pleural cavity, and in the direct surgical treatment of hæmorrhage into the lungs which may open a new method of dealing with tuberculosis; and lastly, upon which I propose to dwell, there is the great lesson derived from the care and treatment of our brave men who have broken down in nerve and mind through the overwhelming stress and strain of action against the incessant terrors of high explosives. The treatment of these cases is one of the most difficult as it is the most responsible in medical art, for, to succeed, it requires special qualities of heart and head that are not pre-requisites in the other departments of medical practice. As is well known, most cases of "shell-shock" carry no wounds; they are rarely to be found in the front trenches, and they most frequently occur at the base or, it may be, whilst on leave. It is true that some have suffered from direct and definite physical injury to the nervous tissues, owing to the concussion or percussion of high explosives, which suddenly burst with a pressure, positive or negative, varying from 100 lb. to the square inch. As we know from the results of aircraft bombs, doors and windows may be blown in or they may be drawn outwards; but the majority of shell-shock cases are those who have suffered from the emotional strain of long-continued thinking and worrying over the anxiety of trench fighting with its horrors, harassing uncertainties and appalling sights—the element of "fear," in one or other of its many forms, reacting upon a predisposed temperament, and this is the predominant factor in the emotional disturbance.

I maintain that in every case of shell-shock there are definite mental as well as nervous symptoms, and although this question is both debatable and debated every shell-shock case is a mental case, and he deserves the best treatment his grateful country can give him. Every mental case in this war has been treated in the first instance without the legal sanction of the committing medical certificate, and in the scheme of reconstruction legal power must be obtained to apply the same treatment to the civil population.

For several years before the war there had been a great and deeply felt agitation, in which many of us joined, to ensure that all mental cases in their earlier stages, those that might be described as functional mental disturbances, should be treated at first without commitment into an asylum, because, upon recovery, which in favourable cases occurred within a few weeks, the painful memory of the illness associated with the disabilities inevitable from certification caused these persons to be shunned and avoided in the future. They were hence regarded as not only outside the pale of sympathy, but persons who could not even after recovery be trusted in any responsible position. Upon leaving the asylum they found themselves in a world of their own without friends, without help, and without work. The consequence of having been certified and detained as a lunatic for however short a period meant for them the deprivation

of civil, financial, political, and domestic rights, and there remained an undeserved social stigma, which not only marred their lives, but which also blighted the prospects of members of their family; and those dependent upon them suffered, and were not infrequently drawn down to a lower plane of social life, from which they discovered that an emergence was almost impossible. The subject was for some time looked upon as one demanding immediate legislation, and it was strongly felt that the most pitiable and the most helpless of our fellow-subjects should not be confined and deprived of their liberty without an effort being made to try all other measures first. As a matter of fact, in the treatment of mental diseases, legislation interferes to-day with the legitimate work of the true physician. For these reasons, therefore, several Bills were brought before the Legislature with the view of bringing about a much-needed change; some of these Bills had for their object the establishment of special homes or receiving hospitals for mental patients in their earlier stages; one Bill, such as that introduced into the House of Lords in 1914, aimed at extending to these and similar cases the necessary medical treatment during a period of six months in some approved home; whilst a third Bill introduced into the House of Commons—the Mental Treatment Bill—aimed at treating for a limited period without certification all cases of mental breakdown in consequence of the war, and therefore without the usual commitment into the asylum. Public feeling had thus been gradually prepared, by a criticism of the past, for the wise and considerate treatment arranged for these cases, and so far as the Army was concerned, this was carried out by the courage and the ability of the late Director-General, Sir Alfred Keogh.

As was naturally to be expected, mental and nervous breakdown were inseparable illnesses from an active and strenuous life under conditions of stress and fatigue associated with irregularity of food and sleep and with great and unaccustomed hardships; so that, shortly after the commencement of hostilities, cases of mental and nervous breakdown began to occur and some reached England as early as September 1914. This was the time to act, the fashion of the period had changed and insanity immediately became a matter of national importance. Public opinion had been roused, and a special officer (Col. Aldren Turner, C.B.) was appointed to advise upon their treatment. The first important step was to realise the nature of the cases in order to discover what treatment should be necessary, and what accommodation would prove suitable for them, also what suggestions might possibly be made for the future. It was found that the cases coming home from overseas could be divided roughly into three groups: firstly, those with definite material damage to the nervous system, which might be received either into the ordinary hospitals or into auxiliary hospitals, or even into the central military hospitals without special sections for the treatment of nervous conditions; secondly, those coming under the common term "neurasthenia"—emotional or commotional shell-shock—cases which should be treated either under experts in neurological departments attached to the military hospitals or in special hospitals previously established for the treatment of nervous disorders; and thirdly, there was the group of cases suffering from more definite and well marked mental symptoms, who required special treatment, and preferably in institutions previously adapted for mental diseases and ministering to this particular class before the war, and throughout this new departure the help of the Board of Control has been invaluable to the Government and to the country for their readiness in every way to offer and to expedite the emptying of so many large public asylums of their former civil population so that they might be used for the reception of the military.

In the march of science and in the progress of medical treatment no finality can be applied to such a complicated subject as the care and treatment of mental diseases, but for all three groups named a period of rest in an atmosphere of persuasive recovery was necessary, in order to compose the nervous system of these overwrought soldiers, and this has now been provided for each Army area in France. The mystery attaching to insanity was relinquished, it was properly regarded as a bodily disorder, and a hospital atmosphere under those possessing special knowledge was created.

The cases were treated in specially arranged nervous or "shock hospitals," situated near the clearing hospitals, where they remained until sent to the local convalescent camps, where the treatment was modified to suit individual cases, or where it was continued further until the men rejoined their units. If they did not progress, and the response to treatment was not satisfactory, they were then sent to the base hospitals, whence they were drafted home for further care. As a base in England, accommodation was provided for these cases at Netley, where both a neurological

and a mental department were established and later on, as the cases became more numerous, Netley was used as a clearing hospital, the "nervous" cases being drafted to the 4th London Territorial Hospital, to the Red Cross Hospital at Maghull, and to the Springfield War Hospital; whilst the mental cases, which have already numbered over 9,000, were sent to the Napsbury War Hospital, St. Albans, where over 2,000 mental cases have been treated, and to the Lord Derby War Hospital, Winwick, where up to date over 3,000 mental cases have been received. If the patients belonged to Scotland, then the "nervous" cases were drafted to the Royal Victoria Hospital, Edinburgh, and the mental cases to the War Hospital near Perth, and to that at Dykebar, near Paisley, which has received to date over 2,000 mental cases; and if to Ireland (where already about 1,500 cases have been received), then they were sent to the Richmond Hospital with thirty-two beds, or to the King George Hospital, Dublin (but this does not keep the mental cases), or to the War Hospital, Belfast, with 400 to 500 beds, a few beds being retained for officers. There were in addition various auxiliary and central military hospitals, as well as special hospitals for officers, such as that at Palace Green with its dependencies in London, and that at Craig Lockhart in Scotland, and for men in Ireland the Red Cross Hospital, Hermitage, Lucan, Co. Dublin. There have been very considerable extensions since then to meet the great demand, the number of the mental and combined nervous cases probably not being much under fifteen thousand; but these need not be referred to further here. One additional feature in regard to the present treatment of our mental soldiers needs to be mentioned, and that is the establishment under the Ministry of Pensions of after-care homes for the discharged soldier who has not recovered, and whose condition renders him unfit for further service. The discharged soldier or the "ex-Service man," as he is described, is encouraged to enter a home of recovery or a village settlement, in which he may be further "annealed," and where he is taught some suitable occupation according to his taste and capacity, being thus prepared for a fresh start in civil life. This after-care treatment is a bridge between the hospital and social life, and a great public effort is now being made to provide this school-life in a hospital atmosphere so that the soldier may fill a remunerative gap in what seems in the future to be the very difficult problem of opening up the "serried ranks." It is computed that considerably over 300,000 men have already been discharged from the Army, of whom probably a fifth are those who have been rendered unfit for their previous occupations through various disabling illnesses of the mind and the nervous system, and if such means of restoration are found to be useful, and helpful and beneficial for the military, the lesson is a great and necessary one for the civil population, and legal changes must be obtained to facilitate this treatment without delay.

[The concluding portion of the paper, with the discussion, will be published next week.]

ENGINEERING NOTES.

Electric v. *Steam Haulage in Relieving Coal Shortage.*—The *Railway Review* says that while the question of coal shortage in the United States of America has been brought so prominently to the attention of the public by the recent closing order of the Fuel Administrator, it is interesting to note the splendid work that is being done, and the savings effected by the railroads that have adopted electricity as a motive power on a part of their lines. On the Elkhorn grade electrification of the Norfolk and Western Railway, which is one of the biggest coal-carrying roads in the country, the 270 ton Baldwin-Westinghouse electric locomotives haul a 3,250-ton train of steel cars loaded with coal, en route for eastern points. Previously to the electrification it required three of the biggest modern type of Mallet locomotives equipped with mechanical stokers to haul a train of this tonnage up the Elkhorn grade at a speed of seven miles an hour. Two electric locomotives haul it up the same grade at fourteen miles per hour, double the speed formerly obtained by the steam locomotives. With electric propulsion, the same coal traffic can, therefore, be hauled with about one-third the former number of locomotives and half the number of engine and train crews. Of equal interest is the statement recently made by the Commission of Agriculture of the State of Montana in regard to the use of electric power by the Chicago, Milwaukee, and St. Paul Railway, now obtaining 160,000 kw. of electric power from the hydraulic plant of the Montana Power Co., and the saving in fuel effected by this use of water-power instead of coal has been very gratifying to the State officials. The Commissioner states: "To give an idea of the value of the power which is being generated by these plants, it may be stated that to produce 160,000 kw. from coal would require the yearly consumption of 2,500,000 tons, which, at the average price of $4 which would apply at the points where the power is used, would amount to $10,000,000. When it is considered that the value of this coal is, by means of water-power, being saved each year, and that during the next ten years this saving will, in all probability, be increased seven or eight times, it is not difficult to understand that true conservation consists in encouraging the rapid development of water-power." It has been estimated that the

shortage of coal last year amounted to 50,000,000 tons; the saving, therefore, by this one company alone of 2,500,000 tons of Montana coal amounts to 5 per cent. of the total shortage in the country last year.

Power from a Volcano in Italy.—Over a year ago (December 15th, 1916) a note was given in this column on this subject. According to *Chambers's Journal*, extensions are being added to the generating plant which will increase the output to 55,000 h.p. while a project is on foot for utilising the sources of volcanic heat near Naples, where high temperatures are all met with at a comparatively shallow depth below the surface. These schemes, however, depend upon natural conditions, and it has occurred to an American engineer, Mr. N. B. Wales, that similar conditions could be produced artificially. According to Mr. Wales's plan, two or three tubes should be sunk in the ground where heat is likely to be met with comparatively near the surface, until a temperature of 350° to 450° F. is reached. These tubes are of different sizes, and are arranged one inside the other, leaving space enough for steam to come up between them. Water is to be pumped down the central tube and into the heated crater at the bottom, where it would be turned into steam, and rise up through the space between the inner and the outer tubes to be utilised for generating purposes at the surface. Many areas are said to exist in the United States where the necessary temperature is to be met with at depths of under 5,000 ft.

British Oil.—In a paper recently read before the Institution of Petroleum Technologists, Mr. E. H. C. Craig said that a very large quantity of mineral oil could be produced in this country, and much material now neglected or treated as waste could be utilised for the purpose. There were several minerals from which oil could be obtained in this country, namely, oil shale, coal, cannel coal, blackband ironstone, lignite, and peat, but of these the only one at present utilised was oil shale, and that only in Scotland. This industry produced 320,000 tons of oil per annum, but not more than 60 per cent. was fuel, and the percentage of petrol was negligible. Of the other oil-yielding materials cannel coal was the most practicable, and though large quantities of it were being brought to bank at collieries in this country, it was thrown on the waste heap as useless, while a still greater quantity was never brought to the surface. Of blackband ironstone, there still remained a number of seams that could be utilised. Many seams, also containing both coal, ironstone, and cannel, existed which were not worked because the coal was too thin, but would, if mined for oil purposes, add to the coal and iron supply as well. The cannels in this country would give an average yield of 35 gallons per ton, as compared with 22 gallons, the yield of the Scottish shale companies, which, however, were paying high dividends. The new industry must be started on broad lines and on a large scale, and at least six retorting and refining works could be established without any difficulty.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 27...Surveyors' Institution, Great George-street, S.W., 5 p.m. Annual General Meeting.

Geographical Society, Burlington-gardens, W., 5.30 p.m. Anniversary Meeting and President's Address.

TUESDAY, MAY 28...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. H. W. Fincham, "The Knights of St. John of Jerusalem (Hospitallers) and their London Home."

Royal Institution, Albemarle-street, W., 3 p.m. Sir H. Newbolt, "The Poetry of Thomas Hardy. Lecture I.—'The Dynasts.'"

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. W. Burford, "The Application of Electric Power to Oilfield Requirements."

Zoological Society, Regent's-park, N.W., 5 30 p.m. 1. Mr. N. Taylor, "A Case of Hermaphroditism in a Lizard, *Lacerta viridis*." 2. Mr. C. T. Regan, "Freshwater Fish as Food."

Royal Dublin Society, Leinster House, Dublin, 4.15 p.m. 1. Dr. W. E. Adeney and Mr. H. G. Becker, "The Rate of Solution of Atmospheric Nitrogen and Oxygen by Water. Part I.—The Rate of Solution by thin Films of Water." 2. Dr. G. H. Pethybridge and Mr. H. A. Lafferty, "A Disease of Flax Seedlings caused by a Species of Colletotrichum and transmitted by Infected Seed." 3. Dr. F. E. Hackett, "The Twist and Magnetisation of a Steel Tube in a Spiral Magnetic Field."

REGISTERED AS A NEWSPAPER.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 3...Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Rev. C. Lias, "Germanism."

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Sir Mark Collet, "Rural Housing."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 7.30 p.m. 1. Dr. H. J. S. Sand, "A Cadmium-vapour Arc Lamp." 2. Mr. A. R. Powell, "The Estimation of Tin in high-grade Wolfram ores and the use of Lead as a reducing agent in Pearce's assay."

Geographical Society, Kensington-gore, W., 5 p.m.

TUESDAY, JUNE 4...Gas Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 10.30 a.m. (Annual General Meeting.) Presidential Address by Lord Moulton.

Royal Institution, Albemarle-street, W., 3 p.m. Sir H. Newbolt, "The Poetry of Thomas Hardy. Lecture II.—The Shorter Poems."

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. A. E. Bullock, "Interiors of Famous Mansions."

WEDNESDAY, JUNE 5...British Academy, at the Royal Society, Burlington House, W., 5 p.m. Mr. L. Binyon, "English Poetry in its relation to Pictorial and other Arts."

Geological Society, Burlington House, W., 5.30 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Major M. W. Flack, "The Health Aspects of Aeronautics."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 5 p.m. 1. Mr. E. G. Jones, "A Method for the Colorimetric Estimation of Cobalt." 2. Mr. A. C. Chapman, "Nucleic Acid and its Analytical Examination." 3. Mr. J. N. Rakshit, (*a*) "Opium Wax"; (*b*) "Estimation of Morphine in Opium by Polarimeter." 4. Mr. P. J. Fryer, "The Application of the Valenta Turbidity Test to Mineral Oils." 5. Mr. J. H. Johnston and Dr. A. W. Stewart, "The Valenta and Crismer Tests." 6. Mr. A. W. Blyth, "A New Method of Identifying Starches." 7. Mr. A. L. Bacharach, "Two Plant Products from Colombia, S.A."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Lecture by Professor M. A. Gerothwohl.

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Dr. P. Nelson, (*a*) "The Earliest Type of English Alabaster Table"; (*b*) "Some Unpublished English Alabaster Carvings."

Gas Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 10.30 a.m. (Annual General Meeting continued.) "Report of the Refractory Materials Research Committee" and other business.

THURSDAY, JUNE 6...Linnean Society, Burlington House, W., 5 p.m. 1. Mr. C. C. Lacaita, "A Revision of some Critical Species of *Echium* [Viper's Bugloss], with a description of *Echium judacium*." 2. Captain A. W. Hill, "Experiments with *Cyclamen*." 3. Messrs. R. Paulson and S. Hastings, "On the Relationship between the Symbionts in a Lichen." 4. Mr. W. C. Worsdell, "Abnormal Apple-blossoms and Fruit."

Chemical Society, Burlington House, W., 8 p.m. Dr. H. T. Brown, "The Principles of Diffusion: their Analogies and Applications."

Royal Institution, Albemarle-street, W., 3 p.m. Colonel Sir F. Younghusband, "The Abode of Snow: its Appearance, Inhabitants, and History." (Lecture III.)

FRIDAY, JUNE 7...Royal Institution, Albemarle-street, W., 5.30 p.m. Sir Boverton Redwood, "The Romance of Petroleum."

Astronomical Society, Burlington House, 5 p.m.

SATURDAY, JUNE 8...Royal Institution, Albemarle-street, W., 3 p.m. Professor C. J. Patten, "Problems in Bird Migration." (Lecture III.)

NOTICES.

TWENTY-SECOND ORDINARY MEETING.

Wednesday afternoon, May 29th; SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., in the chair. A paper on "Organic Chemistry in Relation to Industry" was read by DR. MARTIN O. FORSTER, F.R.S., Treasurer of the Chemical Society, and a Director of British Dyes, Ltd.

The paper and discussion will be published in a subsequent number of the *Journal*.

EXAMINATIONS.

The results of the Advanced and Intermediate Examinations (Stages III. and II.), held from March 18th to the 26th, were sent to the centres concerned on the 23rd inst. It is hoped to send out the results of the Elementary Stage early in June. The time-tables for the 1919 examinations will shortly be sent to all centres. The first examination will commence on Monday, April 7th, and finish on Monday, April 14th. The second will commence on Monday, May 26th, and finish on Wednesday, June 4th.

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

THE MENTAL EFFECTS OF THE WAR AND THEIR LESSONS IN REGARD TO MEDICAL AND SOCIAL RECONSTRUCTION.

By MAJOR SIR ROBERT ARMSTRONG-JONES, M.D., R.A.M.C.

(*Continued from p.* 443.)

It is urgent and necessary that the disability which occurs through a mental illness should be promptly dealt with, and it is one of the objects of this paper to hasten this movement as one of the most pressing and imperative claims in the great scheme of reconstruction, and I desire to emphasise this point with all the earnestness and force that a special experience of forty years can command. It is not because there are any violations of personal liberty possible under the present lunacy system that this movement is pressed, for I do not think this is the case, but it is because the poor have no opportunities, such as are already permitted to the rich, to obtain voluntary treatment for a mental illness that a demand for a change in the law is made, and every doctor knows that certification has the effect of retarding treatment. There is no allegation made to-day at all that patients suffering from a mental illness are detained longer than is necessary, nor that the patient is deprived of his liberty for corrupt motives, and it is believed that the licensed houses of to-day, both large and small, supply a real social want. There are many families who prefer the privacy and comfort of a small home to treatment in a large institution with a mixed population; in addition to which there is the natural desire, where a stigma may be reflected upon the relatives in consequence of the certification and commitment, that secrecy should be preserved and exposure avoided, which are believed to be easier in a small establishment than in a large one not limited to the immediate domestic life of a few persons.

Statistics have frequently been presented in regard to the rapid recovery of mental cases during the earlier stages of this illness. Col. Toogood, R.A.M.C., has referred to the recovery rate in 23,000 cases during the first thirty-one days of treatment; Col. Nathan Raw, C.M.G., R.A.M.C., has presented publicly the statistics relating to over 6,000 cases; and Dr. James Carswell, now one of the Deputy Lunacy Commissioners for Scotland, has related his own experience of over 1,000 fresh cases annually, with the result that from 42 to 56 per cent.

of all cases coming under their care, and that of others, recover and are discharged within four weeks of the commencement of treatment. We know, further, that of all the cases which recover in the London County Council Asylums, 65 per cent. leave the asylums within the first twelve months of their admission.

Many patients are extremely susceptible to the suspicion of detention, and are most sensitive to any notion of restraint or confinement: indeed such a feeling prevents their appealing for help and advice. To a morbidly sensitive individual, the idea of the deprivation of personal freedom retards treatment, whereas if assured that he could receive voluntary treatment based upon voluntary residence, viz., the treatment which approximates the hospital treatment for bodily ailments, it would be widely appreciated, there would be no resentment, and recoveries would be expedited. During the last year of which we have a record—*i.e.* the Report of 1916 by the Board of Control—over 18,000 persons in England and Wales were certified as suffering from their first attack of mental breakdown and admitted into asylums, with the consequent limitation of usefulness to themselves and their families through the stigma attaching to commitment. If legal sanction were given, with proper safeguards against designing persons making a profit out of affliction and illness, and if the care of mental illness were properly guaranteed—which the State has done in the case of venereal diseases by prohibiting treatment by quacks, advertisers, and other improper persons—and if the State would help to pay for treatment in ordinary hospitals, there would come forward a body of qualified men and trained women eager to give their services in the work of helping to right the most delicate disturbance of that very complicated human mechanism—viz., the organ of the mind. Every doctor knows that before his patient is certified, all the friends beg him to try other means before asylum commitment, which registers the insanity and perpetuates the stigma. It is felt that the work of mental healing must begin long before the certificate becomes necessary, and although this may not be the place to discuss the details, opportunities must be given to the mental patient to be treated early. There should be no taint of pauperism in the relief of any unavoidable illness, particularly an illness so entirely disabling and so appealing as is a mental illness, and the Local Government Board, or some other Department, should supplement—preferably not from the Poor Law—the maintenance of mentally ailing indigent persons in the ordinary general hospitals or in some suitable homes of rest. If the certificate becomes necessary (and the need for asylums such as those which now exist will always be justifiable for the detention of dangerous patients), it should as now be authorised after the justice had seen the patient, but the patient must not be brought before the justice as is sometimes done at present, with the result that the patient feels himself to be a suspected criminal and not a sick person, which greatly retards his recovery. We need legal power to treat mental patients like other patients, but preferably, and in order to avoid abuse, for a definite and fixed period. Power must also be granted to poor persons to enter the county asylums and the other public mental hospitals voluntarily, but to be only detained during the early phases of the illness and with their own assent. It is an anomaly to insist upon an aggression on personal liberty before a patient can receive adequate and proper treatment for a mental illness, whilst his own assent is now readily accepted for his treatment for a bodily disease. A mental disease if not cured is of far greater moment to the sufferer, as well as more serious to his family and dependants, than is a bodily disease, and yet he has to wait until his disease is confirmed before he can receive remedial assistance. The success which has been obtained during the war in the care of mental patients without any certification is surely sufficient justification for its limited extension in peace time; at any rate, it is one of the strongest and deepest lessons of this great war.

Lastly, I have met many young men, as helpers in operating theatres, X-ray and electrical departments, and in bacteriological laboratories, who before the war were engaged in business and commerce. In their new work they have suddenly discovered ideal and congenial vocations, and I should personally like to see all the medical schools throughout the country offering "free places" to these young men after the war, with the object of affording them an opportunity of helping to fill up the depleted ranks of the medical profession. I consider that every military hospital should possess workshop schools open to soldiers during their convalescence and to prepare them for future employment, but "Labour" so far has not permitted such instruction to be given.

Labour.

The submarine and the aeroplane have been the surprises of the war, and they have probably

brought along with them great changes in the conditions of trade as well as altering the whole economic conditions of the British Isles, and it is incumbent upon this country not only to use every effort after the war to extend our home industries but to commence now. There are already signs that labour is being organised upon a national rather than upon a class basis, and this will prove to be the best corrective for the deep-rooted misunderstanding between Capital and Labour and between employer and employed, which started as far back as the beginning of the industrial revolution one hundred years ago.

In order to rebuild the nation's fortune, or indeed to live at all and to pay for the war, the great object is to put out the maximum capacity of our people; in other words, there must be a greater output of work, which means that we must have more machinery and also import more raw material, for which we must have ships. This will produce more goods for export, but increased production depends also upon good feeling and friendly relations between employer and employed. It is no exaggeration to say that some of the trade unions have compelled the limitation of work so as to restrict the output. Of this I have personal knowledge. Neither is it any exaggeration to state that employers have also in the past kept down the rate of wages because the workmen earned too much. If the country is to be reconstructed upon progressive lines, and if we are to profit from the lessons of the war, we must recognise there are no royal roads to reconstruction; but certain general considerations hold good in all human affairs, and one of these is good feeling and goodwill. "Equality is the great human formula of the coming revolutionary era," and there must be a realisation that socialistic theories are fatal to us, for they only tend to keep the agitators occupied, and as long as industrial difficulties last, so long will the position and the livelihood of socialist *doctrinaires* be maintained, for they live and thrive only upon suspicion and strife between master and workman, and their object is to stir it up. It is certain that more can be done by voluntary organisation than by State control, as we have seen in shipping construction, and at present there is a strong feeling on the part, both of employer and employed, to keep off as much State interference as possible, and the sure method of progress is to foster a good feeling, for the average workman has no ill-will against his employer, and if industrial unrest is to be avoided each should know the other better. No bargain has ever been considered valid and good unless both parties were pleased, and the essence of industrial peace is to recognise each other's views. It is believed that joint industrial boards composed of representatives of employers and employed in each trade should be appointed, as was recommended by the Whitley Committee, in order to discuss any new departures or to alter any old grievances. Some of the trades have several of these boards, whilst others have none. The use of machinery and the entry of women into hand trades, imply new and greatly augmented methods of production, and the labour of women needs to be taken into serious consideration in all schemes of reconstruction, for it is estimated that nearly one and a half million more women are employed since July 1914 in work previously done by men. About half a million women have replaced men in industries, another half million in commerce, over a quarter of a million on the land. and a quarter of a million in Government establishments. The National Union of Women Suffrage Society is pledged to uphold the continuation of women's employment, as well as their entry into the professions, and their right to university degrees. One of the greatest social and economic movements since the war has been the organisation of work by the quarter of a million of women on the land, who before the war numbered less than a hundred thousand. Upon the return of the men there must be some means of redistributing the women, and some form of insurance guarantee should be instituted so that the employment shall continue, or if not. then to ensure that there shall be some security of support for them temporarily. It is for these reasons that a trades council organisation in each trade should consider and advise as to rates of pay, which are the most fertile sources of labour disturbances, for these can always be settled by mutual goodwill. In order to provide the fullest information about work an information bureau or a special labour intelligence department needs to be permanently established in connection with the Ministry of Labour, the Board of Trade, or the War Office during demobilisation, and it is earnestly hoped that Labour will help to absorb those who have learnt new trades in consequence of wounds or damage to limbs. Already it is believed that over one hundred committees have been appointed in connection with the work of the Minister for Reconstruction, but what we most want is liberty of action and freedom for as

much progressive organisation as can be obtained. It is hoped that these committees will not permit the great activity in regard to agriculture to falter or fail, for it has been shown that there is a great scope for the development of rural industries. We have already learnt a lesson as to what might have happened when we were threatened with starvation and when shortage of food might already have decided the war. There will be great opportunities for providing facilities for the transport of material in rural areas when the time comes for the disposal of light railway material, motor lorries, traction engines, barbed wire, timber for housing and concrete for building material; but work must be carried on with good-will. So long as "class" feeling can be avoided—and class feeling can best be interpreted as "privilege": a standing example of this was the refusal of the Amalgamated Society of Engineers to join the other trade unions in negotiating with the Minister of National Service about man-power in Glasgow—so long will the destructive canker of strife be prevented from destroying masters and men alike. We have seen what "class" war has done in Russia; not only has it been fatal to public order and liberty, but to the whole of the industrial life of the country and to democracy; and unless we secure industrial peace the energy of the country will be consumed, and our best efforts in all other directions must be dissipated. The defensive leagues which employer and employed have already set up, the latter through the federation of workpeople representing their various trade unions, and the former by the federation of British industries grouped in the National Employers' Federation, are, in my opinion, a healthy sign, and they show the desire for fair play which makes for ultimate friendship and encourages mutual self-respect, for they are leagues for protection and defence, and it is perfectly well known that when people do not defend their interests, no justice can be secured. Before trade unions were established it is certain that workpeople were at the mercy of their employers, and before the federation of employers was formed these also were unable to defend themselves; yet it may be said that the trade unions represent mainly the skilled artisans who are only a fraction of the vast army of British workmen; but it is eminently satisfactory that out of the defensive societies representing Capital and Labour has arisen the National Alliance of Employers and Employed, a society formed to discuss common interests and composed of Labour leaders and employers, but with a neutral chairman. It is recognised that there must be a give and take—a rational compromise—if we are to profit by the lessons of the war. The form of the industrial tribunals matters little, it is the spirit of the disputants which is the essential thing. The standard of life must not only be maintained, but it must be raised in regard to Labour, and in order to do this wages must be good, but the employer is unable to pay good wages until he sells his goods, and for this he must have market facilities both at home and abroad. Imperial expansion is necessary for our trade, and protection against the foreigner has been proved to be of vital importance during this war. The common dangers to be avoided in regard to Labour are internal disputes and strife.

Law.

Among the most thoughtful practitioners in the law the war has created a very definite mental self-examination, which has revealed a rising discontent with things as they were, and this feeling has crystallised out into suggestions which have been formulated into a definite demand for changes in the law.

It is now realised that more must be done for the child, whether legitimate or otherwise, and the law in regard to adoption needs revision. The duty of parents concerns the State, and the State has, by the Children Act of 1908, recognised that a child may be removed from the "custody, charge, or care of parents unfit to be so entrusted."

In regard to the child, who must be viewed as the innocent third party to the contract of marriage and itself not a free agent, the State must ascertain whether parents are fulfilling their duty and, if they are not (upon such grounds as desertion, prolonged separation, chronic drunkenness, or confirmed lunacy), then the anomalous position of parent thus created should be terminated and the duties undertaken by others, because the permanent detriment to the child is also a hurt to the State. This matter has been seriously taken up by the Marriage Law Reform Committee.

It may be incidentally remarked that parents and children must be properly housed, and at least 300,000 homes will be needed after the war. In my opinion, the clauses of the Workmen's Housing Act of 1909, which adopted that of 1890, should be repealed if individual action is not to be paralysed in respect to housing, and the futile restrictions then set up should be removed if the occupants of cottages are not to

be pauperised by social schemes maintained out of the rates. The Government has now definitely recognised the need for action in regard to housing on a large scale, and the President of the Local Government Board has promised substantial aid, but I maintain that the interests of individual exertion and personal effort must not be discouraged.

The law of lunacy is another consideration which urgently and pressingly demands a change; public opinion is ready for it, and the war has taught the country a powerful practical lesson in regard to the care of early mental illness, The Poor Law for a long period has been waiting for the psychological moment in order to be reconstructed, and the changes recommended by the Maclean Committee will prove, if carried out, to be of far-reaching social importance; but whilst the claims of the deserving poor demand a generous consideration, the class of poor persons must not be increased by recruits from those who refuse to work and whose poverty is consequent upon idleness.

The President of the Law Society (Mr. Samuel Garrett), who represents 90 per cent. of the legal profession, has called public attention to the immediate need for changes in the law, because, as he pointed out, progress and civilisation depend as much upon the rapid and economical administration of the law as upon its just application. Indeed, he gave a significant warning that unless changes to effect these requisites were included in the scheme of reconstruction, the legal business will tend more and more to go away from lawyers into the hands of laymen, who are already approached by a growing body of disputants eager to have their affairs settled by arbitration or by compromise based on common-sense and special expert knowledge rather than to wait for the decision of the lawyers. To ensure these advantages to the public, the President suggested the appointment of a special Minister of Justice, and it can be no detraction to the carrying out of this suggestion that so many other Ministries have already been appointed. Possibly this fact would tend to favour rather than to postpone the proposed new Ministry, for it would then follow precedent which appears to be a great factor in law. It is certain that if all legal affairs were under one control, there would be less overlapping, less extravagance, and inefficiency, and there would be more supervision, concentration and expedition; at any rate, a Ministry of Justice would give effect to the unfulfilled desires of lawyers for over half a century.

There are many other points that call for legal sanction in the near future; the so-called Land Question is one. Means are needed to acquire land by public bodies for small-holdings and for the settlement of the discharged soldier as well as for cottages; also to guard against conditions that may tend to suppress individual effort and private enterprise through the formation of trusts and "combines," such as we have recently witnessed in the amalgamation of banks, insurance companies, and even the milk supply. But I fear to dwell further upon these topics, some of which (such as the protection of our trade and commerce) may be controversial, and this paper has already exceeded the limits of your patience.

DISCUSSION.

The Chairman (The Right Hon. Lord Sydenham, G.C.S.I., G.C.M.G., G.C.I.E., G.B.E., F.R.S.), in opening the discussion, said the paper covered an enormous variety of subjects, and provided an immense field for thought. The war had already produced great and far-reaching results upon the economic life of our nation and every nation that had become involved in it. For good or for evil it must profoundly affect the whole mentality of the people and their attitude towards questions of every kind—foreign, domestic, and social. It required forty years of education, deliberately designed, to bring the German people into the state of mind which made the war absolutely inevitable; but less than four years of the education the war had given had sufficed to change our whole outlook upon most great affairs. Peace-loving nations had been obliged to convert themselves into armed nations and to sink all other aims in the one great object of waging war. The case of America was, perhaps, the most remarkable of all, for America lay far distant from all the theatres of war and was not directly threatened in her own territory. The vast efforts that America had made since she realised that everything she cherished was at stake, meant a revolution in the ideas and ideals of Americans which nothing in the world, except the revelation of the German objects and the shameful brutality of German methods, could ever have brought about. For this country, and for all the warring nations to-day, the great question was: After the war will the good or the evil dominate our life? The author had emphasised the effects of the intense strain upon our troops at the front, and had said that the effects of shell-shock were both physical and psychological, and the lesson he drew, namely, that those so-called mental cases required special treatment of their own, was a very important one. It was intolerable, for example, that the soldier suffering from shell-shock or nervous breakdown, which might be quite temporary, should ever be subjected to the conditions of a lunatic asylum. He agreed with the author that the law of this

country with regard to lunacy, and the methods of treating what were called mental cases, might need substantial revision in the future. In no previous war had so great a stress been thrown upon the fighting man, and a proportion of losses which was formerly considered as disabling any unit which suffered it, had not produced that result in the present war. Men had shown greater endurance than was manifested in the wars of the past, although the trials imposed upon them had been more severe, proving that the amenities of modern life had not produced the results that might have been expected. The educated soldiers and sailors of this country had shown, during the present war, a physical and psychological endurance and a shining heroism that had never been surpassed. War, as the author said, had proved a great teacher, because it had brought home to the many what before was only realised by the few. Thus the employment of the German U-boats in ways of the blackest piracy might have the effect of regenerating the whole of the agriculture of this country, and the phrase "Back to the land" might become a reality, which, but for the war, might never have happened. With regard to temperance, it lay at the root of most social reforms in this country, and the work of the Liquor Control Board had effected a transformation. An object lesson of all that temperance could accomplish had now been provided, and the facts which the author stated proved to the hilt all that reformers had urged in the past with little result. The whole question of the safeguarding of infant life had assumed a new aspect of seriousness during the war, and the value of infant life was now understood better than had ever been the case before. With that question the subject of venereal disease was most intimately connected. That huge evil was ruinous to the birth-rate and to the national health and vigour, and he thought it was now beginning to be understood by the masses. If that was so, measures which were formerly impossible would soon be demanded by the people themselves, even if they involved, as they must, certain restrictions on the liberty of the individual. Medical science, as the author had indicated, had received a new and striking impulse during the war. Many new discoveries had been made which would be of permanent value, and the medical profession would probably have in the future largely increased powers for good in all matters relating to the public health. The effect of war upon the attitude of labour opened out an immense field for thought. Upon sound and harmonious relations between labour and capital the whole economic future of this country largely depended. There had been faults on both sides, but measures were now being taken to bring about a better understanding between Labour and Capital. The mass of the manual workers were sound at heart, although some of them seemed to be too easily misled. If, however, Socialist theories were ever translated into action, the result would be national bankruptcy and national ruin. The logical results of the doctrine of the class war, preached so diligently by Karl Marx, were now being seen in Russia, and it was interesting to note that that purely German doctrine had been propagated in Russia largely with German assistance. If this country emerged from the war with the position of the Empire safeguarded, and its rights and the rights of other nations vindicated, we should find ourselves at a new parting of the ways. We could, if we wished, rebuild our national welfare on much broader lines than before, and in time repair the heavy material losses that the nation had been called upon to sustain. If that opportunity came it would be due to the splendid heroism of our fighting men, to the cool courage and devotion of our mercantile marine and fishing population, and to the strenuous war work of patriotic men and women of all classes. For the sake of those who had fallen and suffered, the problems of reconstruction must be approached in a spirit of harmony and goodwill. As the author had said, the mingling of all classes in the field and in war work of all kinds ought to teach the great lesson of common sacrifice for the State and the Empire. If that lesson was taken to heart, if party and faction could be abolished, and if we could get rid of the party machine, which had corrupted our politics in the past and had created most of our difficulties during the war, then we could surely build up a purer, healthier, and happier national life, in which all honest workers, by brain or by hand, could share as they deserved.

Lord D'Abernon, G.C.M.G., said that with regard to drink and drink control he could re-echo the optimistic note sounded by the author. The results of the various experiments and measures which had been carried out during the last three years had far exceeded the expectation of those most intimately concerned with the work. Apprehension was felt by some that at the end of the war this country would return to pre-war conditions, but he thought that throughout all classes there was a general feeling that pre-war conditions with regard to liquor were extremely unsatisfactory, and when the men had been repatriated there would probably not be anything like the agitation anticipated by some for a return to pre-war conditions. The effect of recent work had been not only an improvement in the number of cases of drunkenness, but also a very great increase of experience in dealing with the question. Consideration of the subject must not be limited to merely restrictive operations; increased attention should be paid to constructive work, and to placing before the people healthier opportunities for refreshment and recreation. The result of the work of the Liquor Control Board would, he believed, induce many people to devote themselves to a more scientific and physiological study of the question than previously obtained, and from that might ensue the utmost benefit to the nation.

Although the measures taken by the Board were severely restrictive of the previous habits of the working-classes, in no part of the country had the reception of those measures been other than sympathetic and intelligent. Most valuable advice and guidance had been furnished by trade union leaders; he could not call to mind a single instance in which the attitude of labour leaders had been unsympathetic to reform and to progress.

MR. SAMUEL GARRETT (President of the Law Society) said the branch of the legal profession with which he was connected felt the time had now come when the proposal to appoint a Minister of Justice—first made about a hundred years ago—should be carried into effect. The appointment of such a Minister was an absolute necessity if the legal profession in this country was to do its duty to the public in the reconstruction of society which it was anticipated would take place after the war. The legal machine did not consist merely of judges and lawyers; it consisted also of a vast army of men engaged in clerical and administrative work at the Law Courts and at the various county and local courts. The management of such staffs required a Minister of Justice, with an adequate staff under him, to act as an organising and co-ordinating head. He was convinced that with proper organisation the administration of justice could be expedited and cheapened to a very great extent. One criticism made of the proposal to appoint a Minister of Justice was that such a Minister existed in fact, though not in name, in the person of the Lord Chancellor. He believed, however, that the Home Secretary also considered himself to be a Minister of Justice, and it was that dispersion of energy and functions that led to overlapping, to inefficiency and to extravagance. The Lord Chancellor had to devote a great deal of time to his work in the House of Lords, as the final Court of Appeal for this country, and in the Judicial Committee of the Privy Council; he was also Speaker of the House of Lords and his duties in connection with his judicial and ecclesiastical patronage occupied much of his time and attention. In addition to that, he was expected to manage, organise and control the legal machine, and it was impossible for one man to accomplish all that work. With reference to the admission of women into the legal profession, the war had effected an entire change in the economic status of women, and he believed it had also effected a change in the minds of members of the legal profession towards women and their aspirations to have every opportunity of earning their living. A few days ago the Law Society received a resolution passed by a local law society in Lancashire approving cordially and unanimously of Lord Buckmaster's Bill to legalise the admission of women into the profession. The Council of the Law Society had by a majority adopted the other view, although their opposition was not based on the merits of the proposal but merely on the view that it would not be fair to make such a vital change in the constitution of the profession while so many of its members were away on active service. The matter, however, concerned not only the profession but the general public, and the entrance of women into the profession would have a most vital and beneficial effect in obtaining alterations of the law with regard to the custody of children and other matters especially affecting women.

THE REV. FREDERICK MANN said he thought the severest critics of the Church would be found within its borders, but it was desirable, on account of the desire for the reconstruction of the whole fabric of our commonwealth upon the surest foundations, that there should be no feeling that the Church was contented to enjoy its privileges and at the same time deny its responsibilities. The Church suffered from the influence of custom and prestige and prejudice that had built around it certain bulwarks which had separated it somewhat from much that was good and true in the national life, but no one could read the utterances of bishops and clergy without seeing that many felt there was a great deal that would have to be turned upside down, in order to bring about that higher civilisation and those higher ideals of conduct which the Church was supposed to promote.

MR. A. H. TREVOR (Commissioner, Board of Control) said that, with reference to the alteration in the lunacy laws referred to by the author, at the present moment no one could take charge of a person for payment, detain him as a lunatic, or receive him to board and lodge, unless that person was certified. The members of the Board of Control all thought that the law was in that respect too stringent, and suggested that a limited period of time should be allowed in which a person suffering from incipient insanity and showing signs of mental disease should be dealt with by experts and have the very best treatment without attaching to him the stigma of lunacy. In the second year of the war a Mental Treatment Bill was brought forward which, for the period of the war and six months afterwards, enabled such treatment to be given to people suffering from the stress brought on by the war. It was very important that that should apply to the whole of the civil population, but if that special treatment was to be given it was important to ensure that it should be the very best treatment, and that unqualified persons should not be able to detain people as lunatics. The Board of Control had had the opportunity of laying its views before the Committee of Reconstruction and hoped that in due time its proposals would be adopted. A clear case had to be shown if any amendment by legislation was to be secured. The subject was not one which ordinary people knew very much about, and they had to be convinced that the proposals brought forward were necessary and would be beneficial. Until unanimity was obtained amongst the people interested in the subject there would not be the faintest chance of obtaining the legislation required.

Sir Arthur Newsholme, K.C.B., M.D., said that, with regard to the subject of child welfare, the author had referred more particularly to voluntary efforts to promote maternity and child welfare among the population; and, as a matter of fact, voluntary effort was commonly the pioneer of official effort, as officials were the first to recognise. Official effort came in afterwards to supplement and subsidise voluntary effort. With regard to what had been done in the past, if the quinquennium from 1871 to 1875 was compared with the quinquennium 1910 to 1914, it would be seen that the infantile death-rate had declined by 39 per cent., and the death-rate in each of the subsequent four years of life had declined by an amount varying between 41 and 50 per cent. Therefore, taking the whole of the first five years of life, there had been a very remarkable reduction in the death-rate. The damage-rate was more serious and extensive than the death-rate, and the same measures which reduced the death-rate had, during the last thirty years, very remarkably reduced the damage-rate among young children. That had been due chiefly to the efforts of sanitary authorities and of their officials—sanitary inspectors and medical officers of health. There still remained, however, a great deal to be done. Of all the deaths occurring at all ages, 28 per cent. occurred under the age of five years—that was to say, about 140,000 or 150,000 children died every year in England and Wales. Of those deaths more than one-half were due to infections, and it was public health efforts in the broadest sense of the word—including housing and improved nutrition, as well as precautions against disease—that were needed to reduce the present loss of life under the age of five years. The hope of the future lay in the co-operation of voluntary workers with official workers. Some people thought that a Ministry of Health could at once accomplish all that was required, but that was not the view of those who had been working for the establishment of such a Ministry, and who knew the need for it. They realised that after the Ministry of Health had been established there would be much uphill work to be done year after year, although that work would undoubtedly be more easily accomplished when the dissipation of energy caused by the fact that a number of bodies, central and local, were engaged in the same work was avoided. One great advance that had been made in the last few years was that it had been gradually brought home to the general public that the health of the child depended very largely on the health of the mother. The Government was now prepared to help the mother and the infant in many ways. It had arranged for the treatment of venereal disease at centres provided at the cost of the country, and assisted local authorities and voluntary agencies in certain activities by providing an equal amount of money to that spent by those authorities and agencies. Such activities included the provision of midwives and nurses in the poorer neighbourhoods, hospital treatment for special diseases of women and children, crêches, and food; and within the last month the Treasury had consented to grants being given for the maintenance of homes for illegitimate infants where the mother and child could be kept together. There was no reason why that system of the Government and local authorities or voluntary agencies providing equal amounts should not be extended in many directions.

Lieut.-Col. D'Arcy Power, F.R.C.S., R.A.M.C., said the reconstruction the medical profession had to deal with was entirely in the direction of simplification. Thousands of observations had been collected from the clinical side, and when those observations had been correlated some very valuable conclusions would be obtained. The results the medical profession was aiming at were that there should be one State examination that all medical students would be required to pass, after which doctors could take honorary titles from universities; and, secondly, that there should be one central educational establishment for London. Instead of having twelve medical schools in London there should be one large school, which could be equipped with the best teachers from all the existing medical schools. Thirdly, there should be a State examination for nurses. The College of Nurses that had just been established would prove to be one of the greatest things done for nurses for very many years.

Miss J. Halford said that, with regard to the subject of infant welfare, the man-power of the future must depend on the mother-power of the present. In all the work now being done to promote the welfare of mothers and infants, the object was the efficiency rather than the endowment of motherhood, and the work of infant welfare centres and similar institutions, as well as that of the large body of health visitors, mostly attached to local authorities, aimed at the instruction of mothers in the care of their children, and also at the education of school-girls in that important subject. It was very much to be hoped that some of the money now being spent so freely by the Government and by voluntary agencies would be devoted to the object of upholding and increasing the education of mothers.

Dr. H. Rayner said that many years ago he headed a deputation to the then Lord Chancellor advocating the adoption of a clause allowing cases of incipient and unconfirmed insanity to be treated for six months without certification, a similar clause having previously been embodied in the Scotch Lunacy Act. The Lord Chancellor adopted the clause and inserted it in a Bill, which was presented to Parliament for three successive years without being passed. At that time the Lunacy Commissioners were just as much in favour of such a provision as the Board of Control was at the present time. His experience at one of the

largest London hospitals had convinced him of the importance of treating incipient cases of lunacy in the very earliest stages, as he had found that many cases had several physical complications, the removal of any one of which would very often arrest the progress of the disease. He had urged very strongly on the hospital authorities that they should provide a special ward for the purpose of treating cases of incipient insanity, as such patients were willing to enter the hospital for treatment, but would not go to the Poor Law infirmary, and therefore became worse, and finally had to be certified. It was interesting to note that in the twelfth century in Cairo the Mohammedans had a very fine general hospital, in which mental cases were treated along with other diseases.

Dr. T. N. Kelynack said that the welfare work of the present time ought to have a physiological and psychological basis. If the work was merely war work founded on expediency it would not persist; but it would do so if it was founded on vital scientific principles. The great experiments that had been carried out by Lord D'Abernon and his co-workers on the Central Board of Control, formed a striking example to guide and govern those engaged in the work of reconstruction, and they illustrated the working out of physiological and psychological principles. War was of necessity a reversion to a primitive state, and it might be that after the war there would be habits and conditions that would tend to accustom people to primitive ways of life and thought. If Lord D'Abernon and his co-workers were unable after the war to continue their methods of control, of substitution and of suppression, there would be the danger in connection with such an agent as alcohol that it would depress and lower the powers of climbing to those loftier heights which were opening before us, and might make us willingly acquiesce in the primitive conditions now forced upon us. It was necessary to see on what foundation our principles and practice in regard to reconstruction were being built.

The Rev. C. T. Mead Allen said it was crises of unrest such as the present that offered the best opportunities for the promulgation of new ideas and for the development of old ones. Religion made its appeal to the heart, the soul and the spirit of man, but it could do so only through the mind. That being so, the period since the outbreak of the war should have afforded unprecedented opportunities for a great religious revival throughout the nation. No such revival, however, had taken place, and the great mass of the people had been left untouched by the National Mission of Repentance and Hope. The war had done a great deal to break down the individual, parochial outlook. Men wanted a God who was good and great, and nothing else would satisfy them. On the record of the Gospels alone the faith of the people must be rebuilt, and until our national life had been founded upon such a basis of faith there was no hope of a permanent and successful scheme of reconstruction.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, April 30th, 1918; Sir Everard im Thurn, K.C.M.G., C.B., in the chair.

The paper read was—

BRITISH GUIANA AND THE PROBLEM OF ITS DEVELOPMENT.

By Sir Walter Egerton, K.C.M.G., LL.D.

The first European settlement in the territory now known as British Guiana was established by the Dutch so long ago as 1616. Three years previously King James I. had issued a patent granting the whole of Guiana, from the Orinoco to the Amazon, to Robert Harcourt, an ancestor of the present Lord Harcourt, who, as Mr. Lewis Harcourt, was Secretary of State for the Colonies from 1910 to 1915. Robert Harcourt, however, failed to establish a settlement. The Dutch possession was maintained though frequently challenged, and for short periods with success, by the Portuguese, French, and British. until in 1803 it was finally occupied by us, and we were confirmed in possession at the peace of 1814. Though held by Europeans for over three centuries, and in the possession of the British Crown for over one, the territory is still undeveloped and in great part unknown.

Why is this? It would be a mistake to compare its history with that of other lands in the temperate zones colonised and developed from these islands. There is little similarity between the Government and development of equatorial jungles and the lands of Canada and Australia, where our race reproduces itself in all its pristine vigour, and the new population soon becomes fitted for self-government. Let the comparison then be with other lands in the tropics.

British Guiana has an area of 90,277 square miles, of which only the odd 277 are under cultivation, and this in a climate where the sun and moisture force vegetation to its maximum luxuriance and productiveness; where the indigenous forest, covering not less than seven-eighths of its extent, abounds in valuable timber and other forest produce, and is in itself a proof

of the fertility of the soil; where large areas are known to be highly mineralised, from which gold and diamonds to a considerable value have been and are being won by most primitive methods of mining.

Can I make you realise its emptiness? Let us compare the population of the Colony with that of some of our other tropical Colonies.

The population of the British West Indies, in one-eighth the area, is 1,800,000—six times that of British Guiana.

In Ceylon, 4,500,000. British Guiana, three and a half times as large, has only one-fifteenth of Ceylon's total.

The Straits Settlements and Federated Malay States, one-third the size, boast a population of 2,000,000. Fifty years ago that population was only a little more than that of British Guiana.

Why has one developed so wonderfully whilst the other has been practically standing still? It may be said that the failure of the Colony to progress is due to its want of population. That is so; but why has the population not grown more in the century of British administration? Firstly, because, though vast sums were spent on immigration, they were spent chiefly on introducing men to labour on the plantations, with little appreciation of the vital necessity of bringing women also if a permanent increase was to be attained, such an increase as would render immigration ultimately unnecessary. Then, until recently, and partly on account of the excessive number of males, but chiefly owing to insanitary conditions, the death-rate generally exceeded the birth-rate.

Is its stagnation due to its form of government, its climate, or the inherent difficulties of its physical formation? I think each of the three is partly responsible; that one, the second, has been partly overcome, and that, given a successful termination of the present war, a little sympathetic help from the Mother Country, coupled with more firmness and more active interest in its peculiar problems, should take away the reproach that undoubtedly can now be levelled at us—that after over a century's possession of a country equal in size to Great Britain, only an area less than one-fifth the size of Kent is under cultivation, and most of the remainder is still trackless forest and savannah, unoccupied except by a few nomadic Red Indians.

The coast of British Guiana faces north-east, and looks out on the North Atlantic with no land intervening between it and Greenland in the far distant north. Starting from the Venezuelan boundary in $8\frac{1}{4}°$ N. latitude, it runs south-east for 270 miles to within five degrees of the line where the Corentyne River forms the boundary with Dutch Guiana. Inland the Colony extends southwards to within one degree of the Equator. It is therefore well within the equatorial belt of perpetual summer. The climate is damp and hot, and the average temperature on the coast practically the same as in places in similar latitudes in Asia and Africa, such as Colombo, Singapore, Accra, and Lagos. In British Guiana, however, the heat is rendered much less oppressive by the refreshing North-East Trades blowing straight in from the sea. The Colony, however, was, until the latter end of the nineteenth century, considered one of the deadliest for Europeans, and its vital statistics were appalling. Recurring epidemics of yellow fever used to sweep off the non-immune portion of the population, and malarial fever was a constant scourge.

The discovery that mosquitoes are the propagators of both yellow fever and malaria—first guessed at by a British Guiana doctor in 1850—and that quinine, used as a prophylactic, is a great preventive, has changed this and rendered the Colony quite a healthy one, for those living under proper sanitary conditions.

There is some confusion of thought in speaking of climates as healthy or unhealthy. That of British Guiana is not unhealthy where the sanitation is good and the precautions modern medical science prescribes are taken. In recent years much more attention has been paid to sanitation, and year by year the insistence of the excellent medical officers of the Colony is bringing home to all classes of its inhabitants the advantage of taking such precautions.

The administration of the Government is in the hands of a Governor and Executive Council, consisting of the heads of the principal departments and unofficial members nominated by the Governor and chosen from the leading members of the community.

Legislation is entrusted to a Court of Policy, consisting of official and elected members, in which the Government has a bare majority. This legislature, however, has no power to deal with any measures involving the raising or expenditure of public revenue, which is in the hands of a third body, called the "Combined Court," formed of the members of the Court of Policy with six elected financial representatives. In this Council the Government responsible for the welfare of the community is therefore in a considerable minority. This anomalous position

is further accentuated by the Governor being excluded from all participation in the discussion of the Annual Bill for the raising of the revenue of the ensuing year, his place being taken on that occasion by the senior elected member present.

The Governor is generally an officer who has risen in the Home or Colonial Civil Service—trained throughout his life to grapple with all the problems of administration—in receipt of a very large salary, treble that of any other official, and yet the Colony is deprived of his experience and guiding voice in framing the most important enactment of the whole year. All real power—that of the purse—is placed in the hands of the elected members without giving them also the steadying burden of responsibility.

The marvel is that the Colony has done so well under such a Constitution, but under it no well-considered and settled policy for the future can be followed. Only the present is thought of, and everything is dependent upon ever-changing popular clamour.

Many of the best men in the Colony are fully alive to the desirability of a change in the Constitution, but it is unlikely that the Imperial Government will ever face the outcry that would be raised in some quarters, both in the Colony and here, to any scheme for the introduction of the usual Crown Colony administration. The grant of self-government is admittedly impossible. A middle course would be to transfer the administration of the interior to the Governor and Executive Council, leaving the coast strip to be administered as at present; this, however, would throw a considerable burden on the Imperial Exchequer for a good many years. A third suggestion, put forward recently, is federation with Canada. Undoubtedly, if such federation is ever effected, the Canadian Government would establish a local administration which had not only the responsibility for the welfare of the community, but also the power to carry out the measures considered necessary to ensure such welfare and the development of the resources of the rich interior.

Along the whole coast-line stretches a wide belt of shallow water, with numerous sandbanks, so that steamers pass out of sight of land.

The Essequebo, Demerara, and Corentyne rivers are all navigable within tidal limits, but it is only at Georgetown, at mouth of Demerara, that ocean steamers now call. Here, at spring tides, ships cross the bar on a draught of 18 to 19 ft., dragging through a foot or two of soft mud. Delay is not infrequent, but damage, except choking of condensers, almost unknown.

Mr. G. O. Case, the engineer called in to advise as to the best method of defending the coast against encroachment by the sea, and whose firm is now carrying out works in reinforced concrete to protect the most exposed portion of the coast, has recently prepared a scheme for deepening the entrance by the construction of an eastern mole, two miles in length, of the same material at a cost, including purchase of a dredger, of £250,000. For this expenditure a depth of 20 ft. at ordinary tides is expected to be secured.

The first indication of approach to the land is the change in the colour of the water from the deep blue of the Atlantic to that of pea-soup; then the masts of the wireless station and tops of the chimneys of sugar-estate factories appear, followed by the lighthouse and Old Fort. The ship as it enters the river towers above the low land.

Practically all buildings in British Guiana are of wood, and Georgetown is a wooden city. It is, however, a fine-looking, well-laid-out town with wide and straight streets.

Georgetown boasts of being the largest town in the British West Indies with a population of 55,000, or more than one-sixth of that of the whole Colony. The site is reclaimed tidal swamp well below the level of spring tides, and the problem of giving it an efficient sewerage scheme is as yet unsolved. The town is, however, well drained by a system of sluices opening on to the river at low tide.

Although well laid out in rectangular blocks, the intentions of the original planners of the city have, alas! not been followed. The riverside is overcrowded with warehouses, shops, factories, timber yards, and the poorer parts of the town have been allowed to become covered with small dwellings, with the result that from time to time disastrous fires occur, the last, in 1913, destroying a considerable part of Water Street, the chief business thoroughfare, and some thousands of tons of sugar stored in one of the premises awaiting shipment.

Fires are the great danger in all parts of the town, but, where the buildings are properly separated, can generally be confined to the place of outbreak. This was well shown in the case of the beautiful Roman Catholic cathedral, burnt in 1914 owing to the upsetting of a brazier in the tower. It is now being replaced by one in reinforced concrete, a most suitable material, and one which should in time take the place of wood in the whole of the business quarter.

The principal streets formerly had canals running down the centre, with avenues of trees on each side of these canals and on their outer sides, making four rows in all. The Victoria Regia lily was a beautiful sight in some of the canals, with its fine flowers and tray-like leaves, but the canals were also choked with grass, weeds, and refuse; the water in them was stagnant, and as breeding-places for mosquitoes they were a danger to health. They have within the last few years, with few exceptions, been filled in, and both the health of the city and its general appearance have much improved. In place of the canals are grass-bordered gravel paths much appreciated by foot-passengers.

Georgetown is on the right or east bank and close to the mouth of the Demerara River, which is about half a mile wide with a swift-running stream. For ten miles above the town on each side of the river are large and valuable sugar estates. Crossing the river a fair road runs along the coast for twenty miles, paralleled by the railway, to Parika on the Essequebo. It passes through populous villages, chiefly East Indian, who work on adjacent sugar estates and also cultivate large areas in rice, their numbers being augmented, since the lowering of the river ferry fares, by others from Georgetown and its vicinity during the rice season. It is one of the most cheerful districts to drive through. For most of the distance until the Essequebo is approached, the high sea dam shuts out the view seawards, and at high tide the roar of the surf is heard and the spray seen shooting up above the top.

Standing on the railway wharf at Parika one looks across one channel of the Essequebo at the island of Leguan, the corner of Hog Island and, far upstream, Fort Island. The estuary is here twenty miles in width. The local steamer leaves daily for Suddie on the Essequebo coast. From Suddie a succession of sugar estates formerly stretched twenty miles westward. Now only a few remain, but these are large, formed by the amalgamation of several. A large portion of this coast is now cultivated in rice. Here, too, may be seen some of the best coconuts in the Colony. Only quite recently the coast road has been extended and turned inland to meet the Pomeroon River, and give land access to the small settlements along its banks, where coffee and ground provisions are cultivated.

On both sides of the Pomeroon River and on to the Venezuelan boundary is an expanse of swamp, intersected by many river channels of deltaic formation, awaiting reclamation to transform it into sugar or rice land. It is practically untouched. Morawhanna, the headquarters of the district, is a pretty little station. The district is highly mineralised, and there are indications of petroleum on the coast near Morawhanna. It is chiefly in this district that there is the greatest possibility of an increase in sugar cultivation. Some miles up river from Morawhanna is the Government experimental station of Issarora, with a few acres of Para rubber. The trees have made as quick growth as is usual in Malaya, and have been proved to yield as generously.

From Georgetown eastwards stretches sixty miles of similar low coast, of which the first twenty-five miles to Mahaica is thickly populated, and here some of the best sugar estates and largest villages are located. Then the Berbice River is crossed to the town of New Amsterdam, with 8,000 inhabitants, beyond which lies another sixty odd miles of flat coast lands before the Corentyne River and the Dutch boundary. Nowhere, except on the chief rivers, does the occupation extend beyond a few miles from the sea. Some ten miles of the coast on either side of the Berbice River is fairly well occupied, but the remainder of the Corentyne coast and a long stretch of that between Mahaica and Berbice are very thinly settled and require drainage before cultivation is possible.

The only railways in the Colony are two coast lines, one on each side of the Demerara River, owned by the Demerara Railway Company, and a light railway eighteen miles in length built by Sproston's Shipping Company, connecting Wismar, at the head of steamer navigation on the Demerara, with Rockstone on the right bank of and above some dangerous falls in the lower Essequebo.

The eastern line of sixty miles runs from Georgetown to Rossignol on the Berbice, some two miles below its designed and natural terminus at Blairmont, opposite New Amsterdam. The first section of twenty-five miles of this line was built in the middle of the nineteenth century, and is probably the oldest in South America. Much of its rolling-stock is also, I should say, of nearly equal antiquity.

Until the West Coast line was built and this line extended some fifteen years ago, the company paid good dividends, having a remunerative contract with the sugar estates and a considerable passenger traffic. Its experience with the extensions has been unfortunate. The cost was—it is difficult to say why—very much in

excess of estimate. The lines, being ill-equipped, and the termini on the West Coast and in Berbice being in unsuitable positions, without wharves or modern facilities for handling and storing goods, failed to attract the traffic expected. The capital cost of the whole system is in the neighbourhood of £16,000 a mile, and the receipts, even with the Government guarantee of $60,000 per annum, have often been insufficient to do much more than meet the dividends due on the preferred stock. This position has lately been somewhat improved by the cheapening of the Demerara ferry fare and the extension, with Government assistance, of the West Coast line three and a half miles to Parika, on the Essequebo, at a mileage cost of only £3,500. This extension from the former terminus, in a swamp nearly a mile from the sea, to the river-bank has rendered the joint railway and steamer route the most convenient for travellers to and from the Suddie district on the other side of the wide estuary of the Essequebo.

The provision of a wharf and shipping facilities at Georgetown and the extension of the eastern line to Blairmont, the intended terminus, with similar shipping facilities, would probably, notwithstanding its inflated capital, again place the line on a remunerative basis.

A proposal of Mr. Buck, the Colonial Director of Public Works, to carry the eastern line across the Berbice River to New Amsterdam, if possible for anything approaching his estimate, is preferable to extension to Blairmont; would be of immense benefit to the Colony, and would facilitate extension along the Corentyne coast, any such extension being then certain of remunerative traffic.

In the Colony there has always been great dislike and opposition to Government undertaking works of public utility of a possibly remunerative nature, and this extends to the acquisition of existing railways or the construction of new. The success of such a policy in Trinidad, in Jamaica, in West Africa, in Ceylon, Malaya, and elsewhere in the British tropics, is ignored, but within the last year there have been signs of a change in public opinion. It is to be hoped the change *has* occurred, and that it may be permanent, for the Colony would be well advised to acquire and retain complete control of its internal communications both by land and water, so that such facilities may be used and developed solely for the public benefit and the capital and energies of local and outside capitalists focussed on developing the trade, agriculture, and undoubted mineral riches of the country.

Population.

The first adventurers found in the Guianas only scattered tribes of Red Indian nomads. They are a pleasant and interesting race, but have always shunned new-comers, whether white or coloured.

European missionaries have laboured long and devotedly amongst them and induced a few to live near their mission stations, but the bulk of the Red Indians still remain nomadic, and prefer to live, seldom more than two or three families together, in the forest or savannah far distant from men of any other race. All, and especially those who take any interest in the Colony, should read Sir Everard's delightful book, "Among the Indians of Guiana."

At present they are free to roam over all the interior, and, in addition, considerable areas near the coast and on the lower reaches of the Berbice and Corentyne Rivers have been exclusively reserved to them.

At the census of 1911 they were enumerated to the number of 6,950, but the number in the Colony is certainly not less than double.

The rest of the present population of the Colony is the result, not of spontaneous immigration, but of the efforts of the European settlers to obtain labour for their estates—efforts which might have met with much more permanent success had care been taken to introduce the sexes in fairly equal numbers.

The census of 1911 gave a total population of 296,041, increased by the end of 1916 to 313,814, and thus estimated:—Aborigines, 6,952; Europeans (exclusive of Portuguese), 3,705; Portuguese, 9,884; Chinese, 2,827; black and coloured, 152,307; East Indians, 137,850; race unstated, 336. In the twenty-one years 1891–1911 inclusive, the excess of births over deaths was only 5,332, or only 206 per annum! In the following five years to the end of 1916, a natural increase of 8,338, or 1,627 annually, took place, so that, though still very great improvement is needed, the last quinquennium shows a much better position.

The most difficult problem that has confronted the Colony from the time of the first Dutch settlements has been the increase, even the maintenance, of its population and the supply of sufficient labour for the sugar estates. At first the supply was maintained by slave importation from West Africa. When slavery was abolished other sources had to be looked for, and Madeira, China and India have all been drawn upon for immigrants to labour on the plantations.

Labour.

The curse of slavery still hangs heavily over the Colony, and accounts for the antagonism between blacks and whites. The slaves were brought from many parts of the West Coast of Africa, but chiefly from Nigeria, the Congo and the Gold Coast. In their native lands, living under a strict communal system, under chiefs with absolute powers of life and death, they led industrious lives and were excellent agriculturists.

In the last twenty years the small farmers of the Gold Coast have, unaided, created the biggest cocoa-growing industry in the world, with an export in 1916 of 72,000 tons, value £3,847,720. In Southern Nigeria the natives have, unaided, developed the palm oil and palm kernel trade to an even larger annual value.

Wonderful results, but even in these their native countries, living still under the control of their hereditary chiefs and the restraint of ancient customs, it is more than doubtful if the West Africans would be willing to labour day in and day out for a fixed wage for a European planter. The Germans have tried the experiment on cocoa plantations in the Kameruns with indifferent success, even with the help of harsh laws enacting compulsory labour with heavy punishments for defaulters—laws that would never be tolerated in a British colony.

The blacks in British Guiana cannot be relied on to supply the steady continuous labour required on a sugar estate. They do excellent work from time to time in cutting canes and in supplementing the East Indian labour in the fields, but they dislike regular work, and have a most disastrous habit of trying to take advantage of an employer as soon as they think their labour indispensable.

It must not be supposed, however, that the negro in British Guiana has not his useful place in the community, or that he always shirks heavy labour. He supplies the police and the labour for the wharves, he is an excellent mechanic, he does all the carpentering and housebuilding, supplies drivers for engines, motors, carriages and carts. He provides all the labour for the mines and the balata industry. The teaching staff of the schools, many of the legal profession and some of its most successful members, are blacks. The black population takes an absorbing interest in local politics, and the black elector controls the elections. The blacks, too, are the best represented race in the Combined Court, and rival in the fluency and length of their speeches members of our House of Commons.

The Portuguese immigrants were useless on the estates. As might have been expected, the climate proved too hot for field labour by men of European descent, and the Portuguese soon drifted into the towns and villages. They now form the wealthiest section of the community—are merchants, shopkeepers, lawyers, clerks, etc., and have secured a monopoly of the spirit trade.

The Chinese, perhaps the best agricultural labourers in the world, were introduced chiefly between 1860 and 1866. Other shipments arrived in 1853, 1874, and 1879. Fourteen thousand in all were brought, but of these only 14 per cent. were females.

The voyages averaged no less than 102 days in sailing ships fitted very differently from the immigrant steamships of to-day. Sickness and mortality were great, and the small number of females rendered impossible any substantial permanent increase to the population by their introduction. Only present needs were thought of; the labour required was obtained; it was satisfactory, and no one troubled much about the future. Thus the Chinese population has gradually dwindled until in 1911 we find the sexes approximately equal, with a total of only 2,619. Then in 1912 Chinese births first exceeded the deaths. It is satisfactory to note that this excess has since continued.

Anyone interested in the subject of Chinese immigration to the Colony should read Mr. Clementi's admirable history of the subject in his book, "The Chinese in British Guiana."

[The concluding portion of the paper, with the discussion, will be published next week.]

OBITUARY.

Henry Tylston Hodgson.—By the death of Mr. Henry Tylston Hodgson, which occurred at his residence, Welcombe, Harpenden, on May 22nd, in his seventy-fifth year, the Society loses a Fellow of very long standing, he having been elected a Life Member as long ago as 1871. He was Deputy Chairman of the Midland Railway, and also a member of the boards of several other companies. He had sat on the Hertfordshire County Council, was a county magistrate, and in 1903 filled the office of High Sheriff.

HOWARD AND OTHER LECTURES.

Heavy Oil Engines. Four Lectures. By Captain H. Riall Sankey, R.E., M.Inst.C.E. (1912.) Price 1*s*.

Aeronautics. Three Lectures. By Prof. J. E. Petavel, D.Sc., F.R.S. (1913.) Price 1*s*.

Surface Combustion. Three Lectures. By Prof. William Arthur Bone, D.Sc., Ph.D., F.R.S. (1914.) Price 1*s*.

Motor Fuel. Three Lectures. By Prof. Vivian B. Lewes, F.I.C., F.C.S. (1915.) Price 1*s*.

Coal and its Economic Utilisation. Three Lectures. By Prof. John S. S. Brame. (1917.) Price 1*s*.

The Shortage of the Supply of Non-Phosphoric Iron Ore. Two Lectures. By Prof. William George Fearnsides, M.A., F.G.S., M.Inst.M.E. (1917.) Price 1*s*.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 10...Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. E. Hall, "War on and under the Sea."
Geographical Society, Burlington-gardens, W., 8 p.m. Sir Alfred Sharpe, "The Backbone of Africa."

Tuesday, June 11...Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Dr. A. S. Woodward, "On Two new Elasmobranch Fishes from the Upper Jurassic Lithographic Stone of Bavaria." 2. Mr. M. Roberts, "The Function of Pathology in Evolution."

Wednesday, June 12...Colonial Institute, Caxton Hall, Westminster, S.W., 8.30 p.m.
Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Sir Bernard Mallet, "Some Effects of the War as shown in Vital Statistics."

Thursday, June 13...London Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. Sir Arthur Fell, "London and the Channel Tunnel."
Historical Society, 22, Russell-square, W.C., 5 p.m.

Friday, June 14...Sanitary Institute, Municipal Buildings, Taunton, 11 a.m. Dr. W. G. Savage and Mr. T. Lowther, "Disinfection: its place and practical application in Public Health Work."
Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. Sir Oliver Lodge, "The Teaching of Physics in Schools."

Journal of the Royal Society of Arts.

No. 3,420. VOL. LXVI.

FRIDAY, JUNE 7, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

INDIAN SECTION.

THURSDAY, JUNE 20th, at 4.30 p.m. HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "Indian Cotton and the Cotton-Mill Industry." The paper will be read by SIR CHARLES ARMSTRONG, Chairman, Great Indian Peninsula Railway Company.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

BRITISH GUIANA AND THE PROBLEM OF ITS DEVELOPMENT.

By SIR WALTER EGERTON, K.C.M.G., LL.D.

(*Continued from p.* 458.)

It is, however, on East Indian immigration that the great sugar industry has for the last fifty years depended for its labour. The immigrants have been drawn from both Bengal and Madras, but principally from the Ganges valley. They have proved most excellent immigrants, not only on the estates, but afterwards as free citizens.

The system has been one of five-year contracts, and, after ten years, free return passages. Many, however, preferred to remain in the Colony. Here again the benefit to the Colony and to the planter would have been much greater had the numbers of the sexes of the immigrants been more nearly equal. Without doubt more would have settled in the Colony, and the natural increase would also have been greater. At present there are 20,000 more men than women in the total of 137,000, and although the female births annually exceed the deaths, such is, naturally, not the case as regards males.

It is satisfactory to note that the vital statistics of the East Indians on the sugar estates are far better than those of the rest of the population, showing that they live under healthy conditions and are not overworked.

At present the East Indians in the Colony take little interest in local politics; their numbers are steadily increasing, and are already 44 per cent of the total.

In addition to being chiefly responsible for the sugar production, they have created the rice industry, referred to later, and are gradually acquiring more and more land and taking the lead in agriculture generally.

The rapid development of the Colony of the Straits Settlements and the Malay Peninsula has been due to Chinese and East Indian immigration. The Chinese and the East Indian are the races which have so far been found to supply satisfactory immigrant labour for the development of the equatorial tropics. I know of no other races that can compete with them either as labourers for hire on plantations or on their own account. For thousands of years each of these races has learnt habits of thrift and industry in the struggle for life in thickly populated and civilised communities.

Unfortunately the Colony is threatened with a denial of immigration from either India or China, in each case as the result of ill-considered political agitation.

From India, on account of agitation in that country by a few well-meaning but ill-informed and by a larger number of disloyal agitators using misrepresentations of the indentured system of immigration as a means of creating disaffection to the Indian Government. We have here the curious position of a Government sending a mission consisting of a senior civil servant and a prominent native gentleman to examine into the working of the immigration system, praising it highly and reporting strongly in favour of its continuance, and the same Government immediately deciding to put an end to all such immigration.

From China, because the cry of "Chinese slavery" raised in this country in connexion

with immigration of that race to the Transvaal was so effective a party cry that no Colonial Secretary will now face the possible political risk of approving indentured, or even free assisted, Chinese immigration to British Guiana, notwithstanding the fact that as labourers they proved efficient, that those remaining are orderly and prosperous citizens, and that with our improved cordial relations with China, the quicker and cheaper voyage by steam in lieu of sailing ships, the actual shortening of the distance from 12,310 to 10,910 miles by the completion of the Panama Canal, the voyage being reduced from an average of 102 days to not more than forty-five, such immigration could be so much more easily organised.

Let us hope that the difficulty will be overcome, that if indentured immigration is forbidden from Eastern countries it may be possible to arrange for free immigration.

But there is the further problem of keeping in the Colony the population which is there, assuring its natural increase and attracting capital and immigrants of European race to infuse new energy and wider views into the creole population.

At present the best of British Guiana's sons leave it to seek their fortune elsewhere; many go to Canada or to the States, others to the civil services in our Colonies in West Africa. I found many good and efficient officers in Nigeria recruited from the service in British Guiana. British Guiana also furnished some of the managers and assistants on the sugar estates of the Malay peninsula in my early days, and has done the same on the more recent rubber plantations. The confined life in the small coast strip occupied has no attractions for the best of the youths; they leave the Colony and seldom return, shunning the eternal disputes between the elective section of the Legislature and the Government. All this would be altered with access to the interior.

The chief problems awaiting solution are:—

1. Conservation of the present population and increase of the rate of natural increase by improved sanitation, especially in the towns, where the death-rate habitually considerably exceeds the birth-rate.

2. Preservation of infant life.

3. Provision of good water-supply both in town and country, now for the first time made easily available by the discovery of large reservoirs of pure artesian water.

4. Execution of drainage schemes to increase the area of land in the present occupied coast strip suitable for rice and sugar cultivation.

5. Improvement of existing railway by providing it with shipping and storage facilities at Georgetown. It is the oldest railway in South America, and has worse facilities for shipping and landing cargo than when it was built in the middle of the nineteenth century.

6. An immigration scheme to provide, at the Colony's expense in the first instance, immigration of East Indians and Chinese of both sexes in equal numbers.

7. Construction of a railway from Georgetown to Rupununi Savannah, and the Brazilian frontier, tapping *en route* the entrance to Potaro valley. This would at once make cattle-ranching in the Savannahs, British and Brazilian, profitable, and create a large export trade in frozen meat from Georgetown. By immensely cheapening working in the interior, it would foster mining development in Potaro and Essequebo. Men working in the interior could then take their wives and children with them, and settlement in the interior would commence. An immense amount of land would be available for settlers from outside the Colony, who, not accustomed to the semi-amphibious life of the drained coast lands, might be attracted by the more congenial conditions of the interior.

A great development of the timber industry would result, as the line would pass through two hundred odd miles of forest, much of it containing greenheart timber.

The time required for a trip to the Kaieteur Fall would be decreased by one-half, and the expedition made much cheaper and less arduous. Where one tourist now visits the Colony to see the fall, a hundred would as soon as the railway is completed. Every visitor is a possible settler and provider of capital for developing the Colony's resources.

The line is essential for the development of the Colony, and can be justified on this ground alone; but if constructed it can hardly be doubted that, either by private enterprise or the Brazilian Government, it would be produced one hundred miles to a point on the Rio Branco navigable by large steamers, and later to Manaos on the Amazon; and in the more distant future it would certainly be linked up with the South American continental railway system, a counterpart of the nearly realised Cape to Cairo line, which twenty years ago looked an equally impossible achievement.

8. The improvement of Georgetown harbour. Some immediate improvement is necessary, but the Colony's efforts and resources should be concentrated on obtaining the interior

railway. To deepen Georgetown bar to admit ships drawing, say, 25 ft., would probably cost more than the railway, and, although there is much grumbling now, ships big enough for the present tonnage inwards and outwards are easily provided to cross the existing bar. Deep water is only reached seven miles outside the entrance, and erection of moles for that distance would take many years. It should, however, if possible, be included in the railway scheme.

9. And, lastly, such a change in the system of government as may be necessary to ensure a continuous and settled policy incapable of being defeated or obstructed by every passing gust of political agitation.

The present position makes healthy development, and the carrying out of large schemes that require certainty of action and careful finance for a long period, quite impossible. At present responsibility rests with the Government, but all power with the elected members of the Legislature, elected by only a small fraction of the community. It is a position one would expect to find in a Gilbert and Sullivan opera, but not in a British settlement. The position is very similar to expecting a Ministry in England to carry on in a considerable minority in the House of Commons. The experiment has been tried for over one hundred years, and the result is seen in a land the size of Great Britain only cultivating an area one-fifth the size of Kent. If the community is capable of self-government, then self-government should be given. If it is not, then the rational alternative is to place some other authority in a position to carry out, "without fear or favour, affection or ill-will," such measures as, in consultation with the Colonial Office, may be considered desirable for the healthy development of this valuable and rich province, for the welfare of which the British Crown and people are responsible.

Settlement.

The system of land settlement adopted by the Dutch and continued since was the same in the rivers and on the coast. There were no roads, and access to estates was at first by water only; hence each lot was given a frontage on the river or foreshore, and the land behind left unalienated. Owing to extension of cultivation, sea encroachment on front lands, or their gradual exhaustion, owners applied for and obtained title to additional "depths" behind their original allotments, so that now a lot may be only 100 or 200 yards wide, but anything up to five or more miles in depth. The land, when first opened, was covered with courida or mangrove on the frontage, with heavy forest behind. The adopted method of opening up was always the same. Deep and wide trenches or canals were cut from the sea or river inland, one on each side of the lot for drainage, and one down the centre for irrigation and navigation.

The earth excavated formed raised banks or dams, which prevented influx of water from either side. At the river or sea front and at the back other dams were thrown up, so that the estate was completely enclosed. Subsidiary trenches and dams, parallel to front and back dams, divided off the land into rectangular fields of convenient size, so that access by water was facilitated to all parts. In the earlier days all transport was by water. All internal estate transport is still so conducted, and the canes never have to be carried more than about 100 yards. The names of the estates perpetuate the memory of the successive occupation of the Colony by Dutch, French, and English. Thus adjacent estates in Demerara bear the names of Mon Repos, Triumph, and Beterverwagting.

To control the drainage and irrigation water numerous sluices—for which the old Dutch name of *koker* still persists—had to be constructed. The chief were those in the river or sea dam to allow passage of boats bringing supplies and taking away produce and to provide for drainage. A belt of mangrove and courida was always left to protect the front dams.

Water was required for irrigation. The back dam obstructed the flow of the inland water, and as a long line of estates grew up the continuous back dams held up this water, and it was admitted to the cultivation as required. But this supply was unreliable and insufficient, so that gradually estates combined together and, with the help of the Government, the land behind the estates was also empoldered, and the shallow reservoirs thus constructed now run back to where undulating country commences and effectually prevent the inland extension of cultivation or settlement. A very efficient system of irrigation has thus been created.

Georgetown and the estates and villages depend on these reservoirs for water for domestic purposes, supplemented by rain-water collected from roofs.

In 1911 the autumn rains failed and a great drought occurred. At the instance of Sir Charles Cox, the acting Governor, the first deep-boring machinery was ordered, since supplemented by much additional plant. Deep

artesian wells have been sunk and ample supplies of exceptionally pure water struck in Georgetown and on the greater part of the coast, but so far have not been fully utilised owing to the absence of a staff skilled in the fixing of strainers and other apparatus for preventing the choking of the tubes. Most of these wells are "gushers," and the best supplies have been found at depths from five to eight hundred feet.

Sea Defence.

So long as the foreshore is left untouched it changes little, and the tendency is towards gradual silting and extension seawards, but the alteration of the natural drainage, the more recent concentration of this drainage into a smaller number of outlets with greater discharge, the cutting down of the protective belt in some places and its erosion in others, have led to constantly increasing trouble with the sea defences. So serious has this become that the coast is now divided up into sea defence districts, for which bodies of commissioners, presided over by the Director of Public Works, are responsible. A general sea defence acreage tax is levied, the proceeds of which are supplemented by large Government grants and loans. The most exposed portions of the coast are now being permanently defended by reinforced concrete facing to the dams, and groynes of the same material are being run out seawards to stop erosion.

Roads.

At first the only method of communication was by water, but the earth thrown out of the canals formed raised dams easily converted into roadways, and each estate was compelled by law to maintain a road across its frontage connecting with similar sections made by the adjoining estates. The bits of road were often not in the same alignment, and then connecting links had to be constructed on the dams running at right angles. From time to time encroachments of the sea compelled retirement, and new sections had to be formed with similar connecting links joining on to the old portions left in use. Until the advent of motors this zigzag trace was negotiated by vehicular traffic without much danger, but a drive now with a negro chauffeur at the wheel, oblivious of the laws of centrifugal force, is not without excitement. Cars are frequently overturned; many have been the immersions in the deep roadside trenches, and even fatal accidents are not uncommon.

In the whole of this coast zone there is no stone. In places along the coast are what are known as "shell beaches," banks of finely broken up shells from the shell-fish that live and breed in the adjacent mud flats. The surfacing of the dams which form the coast road with hard material suitable to withstand wheeled traffic was therefore a difficult problem. It was solved by the early Dutch settlers in a simple and excellent way. They burnt heaps of the clay soil into brick earth, which spread on the roads—coarse lumps below with finer material on top and faced where possible with shell from the beaches—gives a really excellent surface not unlike the laterite roads of Ceylon and Malaya.

For heavy traffic, however, something harder is now required, and broken granite is brought to Georgetown from the quarries up the Essequebo at Dalli and Mazaruni.

When slavery was abolished the bulk of the black population ceased to labour on the estates and many of them were abandoned. Some were bought by philanthropists in England and presented to the former labourers; some were otherwise acquired by the negroes. Village sites were laid out on the front lands and the people settled on them. The land adjoining the village was kept as common grazing-land, and the back portion of the old estate divided up into farms, to which journeys are made by canoe. This location of dwellings far away from cultivation is very disadvantageous, facilitates predial larceny, and encourages careless and insufficient cultivation, as so much time has to be spent in journeying to and from the farm. Residence on a farm, however, is objected to under present conditions owing to the certainty of increased contamination of the drinking water. So extensive is the canal system of each estate and village that a pleasant day can be spent "going aback" in a punt or canoe.

The only way of travelling into the interior of the Colony is still by water. The mighty Essequebo and its tributaries furnish the chief arteries of communication, running right through the Colony. Above tidal influence, rapids, cataracts, and falls abound, making travelling slow and very expensive. The country is one huge forest with patches of wet savannah or grass within twenty-five miles of the coast, and in the far interior, on the borders of Brazil, larger tracks of dry savannah extending to a total of some 10,000 square miles and affording excellent grazing for cattle and horses. These savannahs adjoin a much larger area of similar country over the border.

At present only a few ranching titles, terminable, as is usual, within a short period, should the land be required for closer settlement, have been issued. Three or four ranchers own large herds of cattle and a few horses. They would be well off if they had a market, but it is impossible to take the beasts to the coast, and sale over the boundary in Brazil is prevented by a prohibitive duty. A few are smuggled over the border.

A fresh attempt is now being made to cut a practicable track from the Kaieteur plateau through the forest, down which the cattle could be driven to a point on the Essequebo or Demerara, from which water transport can be provided. The problem is not an easy one. It is not merely a question of the provision of a practicable track, but also of grazing and resting-places on the way.

Journeys to the interior on business are tedious. In all the rivers, as soon as tidal influence ceases, rapids begin, and ridges of rocks run across, holding up the water behind. The fall may be only a few inches or it may be many feet. The boat has frequently to be dragged through the rapid or unloaded and dragged overland round a fall. Thus boats generally travel two or three together, so that the crews may help one another. Ten miles up stream is a good day's journey. Even the return journey is slow, as it is not safe to "run" many of the falls.

To those on pleasure bent, with ample time, such trips are full of enjoyment. There is an ever-changing scene of forest and hill and mountain. Large flowering trees of many colours, blue and scarlet macaws, screaming overhead or in the trees on the banks, duck and other water birds, including the great Muscovy duck, are frequently seen. Otters, in schools, race up the stream on the appearance of a boat, until, wearying of the struggle, they dive and reappear a quarter of a mile below. At night you may be wakened by the howling of the great red baboons—if near, a truly astonishing noise, and plainly audible for many miles—or by day a glimpse may be got of a group in the top of one of the highest trees. Day after day the traveller passes on with thick forest on either bank.

The trees on the riverside are clothed, choked, in an impenetrable tangle of creepers, the yellow allamanda and a purple bignonia being most striking objects. Once or twice in a day you may pass a small Indian clearing on the bank, or, in the mining districts, a "landing" with a Chinese shop and a scarcely visible foot-track leading to a mining location, or, perched on a high bank, a balata company's supply depôt.

Mining.

Over a very large part of the interior, from the Venezuelan border to the valleys of the Essequebo and Potaro, gold and diamonds have been found in rich and shallow alluvial deposits. Most of the mining has been and is done by small men washing the river gravels in the primitive way common over all the world. These miners are almost entirely recruited from the black population. In places European prospectors attracted by the rich finds of alluvial workers have located lodes. Companies have been formed, capital raised, and expensive machinery taken at immense cost up the rapids; generally the capital has been dissipated in preliminary expenses, machinery, houses and other equipment, leaving little for working expenditure, and gold has not been secured in sufficient quantity to pay the great cost of running a mine in the interior of a country without communications, without facilities for transport of men or material, and where all food and other supplies must be imported and brought up from the coast. Two companies in fairly accessible localities in the Potaro district have done well in dredging in the Minnehaha and Konawaruk; and the former has also a very promising proposition at Eagle Mountain, with a large quantity of proved alaskite formation similar to that of the Yukon district. Its development awaits the conclusion of the war.

The chief river valleys exploited up to the present are the Barima and Barama in the North-West District, Cuyuni and Mazaruni, both affluents of the Essequebo, and the valleys on both sides of the watershed dividing the Mazaruni and Essequebo, and again the valleys in the watershed between the Essequebo and lower Potaro, below the great Kaieteur plateau. No successful mining has been done east of Essequebo, though some gold has been found.

Gold-mining has now been carried on since 1884, when 250 oz. were exported. The output rapidly increased until, in 1891, over 100,000 oz. were produced, and the annual export continued to exceed that figure for twelve years. It has never reached it since, but at the same time seems likely to continue above an average of 50,000 oz. As recently as 1913 some rich new deposits were located, with the result that the output jumped up to over 82,000 oz. Since the war gold-mining has much decreased owing to the great

rise in cost of supplies and the much higher wages to be earned on the coast.

The free adventurous life on the rivers and in the forest has a great attraction for the young blacks of the labouring classes, and the Negro, like the European, is content to work for little and undergo great hardships if there is a remote chance of sudden riches by a lucky find.

At Christmas all these men insist on returning to their homes on the coast, and Georgetown and its vicinity is then full of them driving about in hired carriages, decked out in fine clothes, and determined to make up for the privations and dulness of their bush life.

Since 1884 over 2,500,000 oz. of gold, valued at more than £9,250,000 sterling, have been exported, nearly of all it the produce of shallow placer workings. Only 70,000 oz. has been obtained by quartz milling.

Diamonds are found in the far interior of the Mazaruni and other rivers, often together with gold. At first they were not recognised. The production since 1901 has totalled 125,000 carats. The output has varied greatly, from only 2,000 carats in 1907 to a maximum of 16,400 in 1916, probably due to prohibition of export in 1915, but the average of the four years 1913–16 was in excess of 11,000 carats. This weight is greater than the total of any previous year, so that production tends to increase. That an increase should occur during the war is extraordinary, as the cost of maintaining supplies on the distant diamond-fields has at least doubled.

It must be remembered that all this mining—gold and diamond—is being carried on in a thick tropical forest country by black prospectors, natives of the Colony, who start without the slightest knowledge of geology and acquire all their skill from their fellow-workers. Gradually a class of very efficient prospectors and workers has been evolved, but they work with very inefficient appliances, are unable to sink much below water-level, and in a country where the most highly-trained white prospector would find the greatest difficulty in discovering and following up indications of the metal or stones. Few of the mining districts can be reached in less than a week, and some require two, three, or even four weeks' toilsome journey. These journeys, after the first day, are done in small open row-boats, very strongly built, similar to the "surf" boats used on the open sea beaches in West Africa, and manned by a crew of eight or ten paddlers. Oars are never used, as they could not be manipulated in the rapids or in the narrow channels of the smaller "creeks," as the affluents of the main rivers are locally called. It is in this river traffic that the aboriginal Indians alone mingle in the life of the Colony and forsake their habitual isolation. Some of the boats have Indian crews, and more have Indian or "Boviander" steersmen. A "Boviander" is a man of mixed Indian and Dutch blood. On the skill of the steersman and bowman the safety of the travellers depends, especially in "running" the numerous rapids. They all pass strict tests, and no boat can be taken up or down without certificated men.

All supplies for the mines have to be taken from the coast. Most are imported. Biscuits, salt pork, beef, and fish are the chief staples. There are no towns, no villages, no settlements from the time the tidal influence is left behind, no means of land transport except on men's backs. At the most used landings and at the larger locations there are shops, generally kept by Chinese, at which supplies may be bought and gold-dust sold or advanced upon. That is all. Where mining has been going on in one place for some years a few vegetables may be seen growing, but it is one of the most regrettable features of British Guiana mining that it has led to absolutely no opening up and settlement of the interior, and this is entirely due to the difficulty and costliness of living there and of maintaining communication with the coast under present conditions. The mining locations are spread over so great an area, are so shifting, and the country is so broken and cut up by rivers, that nowhere has wheeled communication been made possible, nor can beasts of burden be introduced. A considerable sum was spent in cutting a track for sixty miles, through the forest of the watershed between the Essequebo and Mazaruni, from Bartica on the navigable Essequebo to the Caburi minefield. This is known as the Caburi road. It has never been used except by a few foot-passengers, being quite impracticable for wheeled traffic, and there are no resting-places. The traffic still goes by the river route.

A similar history attaches to other attempts at road-making in the interior. As soon as mining ceases in any locality the place is deserted, the tracks from the rivers close up again, landings become overgrown, and King Jungle resumes his sway.

Bauxite.

Although mining has hitherto been confined to gold and diamonds, the prospect of the rapid development of a branch of this industry, much more profitable to the Colony, is now in sight,

owing to the discovery in British and the other Guianas of some of the largest and richest deposits of bauxite in the world.

As long ago as 1897, and again in 1910, Professor Harrison, the eminent geologist, who has long held the appointment of Professor of Science and Agriculture, reported the existence of extensive deposits of exceptional purity. The discovery attracted little attention, however, until five years ago, when the Northern Aluminium Company of America applied for leases of areas containing such deposits. Aluminium has, since the outbreak of the war, been found to be so essential for munition and aircraft purposes that the British Government stipulated that any company working the deposits must be under British control. After long negotiation a company has been formed by the Americans interested to meet Government requirements, and the first cargo of bauxite has left the Colony. This company has acquired large areas of land from private owners and leases of a considerable extent of Crown land in the vicinity of Wismar, at the head of navigation on the Demerara River, near the terminus of the little railway connecting the Demerara and Essequebo Rivers. Ships drawing sixteen feet can reach the workings sixty miles above Georgetown.

The bauxite deposits have recently been traced almost from the Venezuelan boundary right through the Colony to the Dutch border. Further deposits have been located in Dutch and French Guiana, and the Guianas probably contain the most extensive deposits in the world, and some in very accessible positions. Should the industry develop on a large scale, local electrical treatment of the raw material with power obtained from one of the great waterfalls is sure ultimately to take place.

Balata.

Another industry that draws men to the far interior is one known by the unpleasing title af "balata bleeding." Balata is the coagulated latex of the balata tree (*Mimusops globosa*), and is a very similar substance to and substitute for gutta-percha. It is used for machinery belting. The tree is found over wide areas of the forest right down to the farthest south, and as its value is generally higher than rubber its collection is a profitable work. The industry is controlled by the Consolidated Balata and Rubber Company, the survivor and absorber of many other companies. In the spring of each year parties are organised and sent up all the rivers of the Colony. They are kept supplied from up-river depôts, and return in the autumn with the dried sheets of balata. Last year the total exports—the greater portion by this company—exceeded 1,500,000 lb., and as its present value is about 4*s.* a pound; the year's crop is worth about £300,000. The cost of collection, however, is considerable.

Timber.

But mining and balata bleeding are not the only industries that take men into the forest. Timber-getting is carried on to a considerable extent for firewood, shingles, charcoal, sleepers, etc. In the case of greenheart the work extends even somewhat beyond the tidal belt. Difficulty of transport, however, confines this industry, except in the case of the Essequebo, to below the falls. Greenheart, the most valuable timber for all under-water structures, is largely exported, and was used for the Panama Canal works.

On the coast lands practically the only products that are much grown are sugar, rice, coconuts, and limes. Coconuts do fairly well. The trees are seldom carefully cultivated, but left ill drained and choked with grass, weeds, etc. Limes flourish all along the coast and river lands. There is some hope of success in production on a commercial scale of lime-juice and citrate of lime. An enterprising private firm has a factory in Berbice; another factory is working on the Essequebo, and a Government factory in the Suddie district. With the assurance of a steady price lime cultivation should become a profitable and popular village industry. The length of the sea voyage to the States and Canada precludes the export of the fresh fruit.

In the lower river reaches are large areas suitable for coffee and cocoa, and except close to the coast, where the subsoil is sour and salt, practically the whole Colony, up to an elevation of 1,500 ft., is suitable for rubber cultivation. Whether, when the price of rubber falls to near the cost of production in Malaya, say between 1*s.* and 1*s.* 6*d.* a pound, it could be grown profitably with the dearer labour available in British Guiana may be doubtful, but the rubber industry has flourished now for over ten years, and there seems little danger of prices falling below 2*s.* for a considerable time. That rubber will grow as rapidly and yield as bountifully in British Guiana as in other countries in the same latitude has been proved both on the Government experimental plots and on a few small private plantations. Unfortunately, in no single case has a sufficiently large area been planted and maintained in cultivation until the bearing age to

pay the cost of a superintending staff and estate organisation. In several cases areas have been cleared and planted, but have generally, owing to lack of funds, been allowed to relapse into jungle. In British Guiana only one plant is carefully cultivated, and that is the sugar-cane. A recent example of the devotion to sugar, to the exclusion of other agriculture, is given in the alteration of the name of the Planters' Association to that of "The Sugar Planters' Association," apparently as an advertisement that no other branch of agriculture is worth local consideration.

This present attitude must be attributed to the great prosperity brought to the sugar industry and the Colony by the war. Before the war, although large and well-managed estates, with plenty of capital and well-equipped with modern machinery, managed on a series of years to do well, others did not, and many men looked about, in a half-hearted way, for other products to take its place, with the result that both coconuts and rice cultivation extended. In 1884, 98 per cent. of the Colony's exports consisted of products of the sugar-cane—sugar, rum, molasses. All other exports only reached £43,000 in value! In the same year sugar-cane products exceeded in value £2,000,000 sterling. Then a change began.

From 1892 onward less than 80 per cent. of the total exports came from the sugar-cane. This was not due, however, to increased cultivation of other products, but to the rapid development of mining, to the growth of the timber industry, and to the decline in price of sugar. It is only within the last decade that the increased exploitation of balata and the very satisfactory development of rice cultivation have taken place.

The value of the sugar products exported in the three war years is considerably greater than in any year since 1884, beyond which my records do not go back. In 1916 it approached £2,750,000 sterling, other produce amounting to £630,000. While in 1884 produce of the Colony other than that derived from the sugar-cane only amounted in value to £43,000, in 1917 rice alone was exported to six times that total.

The history of the rice industry is a curious one, but there is not time to tell it here. Suffice to say it struggled slowly upwards to success against much opposition. It was created by the efforts of the East Indians, and now not only supplies the whole requirements of the Colony, but a surplus of over 13,000 tons for export to the West Indian Islands.

Kaieteur.

No paper on British Guiana is ever likely to be written without a mention of the Kaieteur Waterfall. If access to the interior is ever made easier the Colony should become a favourite haunt of the tourist. There can be seen equatorial forest vegetation in all its pristine beauty. There, too, are sights not equalled elsewhere, and, though in the damp heat of Guiana many may not care to take trips involving much physical exertion, given a few of the conveniences looked for in modern life thousands would certainly visit Kaieteur and some the more distant Roraima.

Only a brief mention of Kaieteur is possible here. The return trip from Georgetown takes nine days; at present there is a good deal of "roughing it," and the cost is about equal to residence in a good New York hotel. The first day is spent in a small river-boat from 8 a.m. to 4 p.m. or later, on a sixty-mile run up the Demerara; thence twenty miles on the little railway connecting this river with the Essequebo. The second day Tumatumari on Potaro is reached in a small and noisy motor-boat. On the third morning there is a run of two hours in a motor-boat, a walk of four miles round a series of rapids, and the remainder of the journey on that day and the fourth in an open boat with a crew of Indian paddlers. On the fifth morning, after a rather arduous climb of one and a half hours through heavy forest, the traveller emerges suddenly on the Kaieteur plateau. The rest-house here and those occupied on the previous two nights are of a very primitive description, but it is to the enterprise of a private firm, Messrs. Sproston's, that the facilities, such as they are, exist on Potaro, and I fear their provision has not been a profitable work. Five minutes from the rest-house the edge of the fall is reached. The scene is astonishingly peaceful. There is a placid and clear river—like the Thames at Henley—quickening its pace as it nears the edge, with here and there a grass-covered rock piercing its surface; the near bank is gently sloping rock partly covered with brushwood and low trees. On the far side high forest. There is no deafening roar as at Niagara, the bottom of the fall is so distant, over 800 ft. It is difficult to realise such a vertical height. Five times the height of Niagara, four times the height of the London Monument, or just twice the height of the top of Hampstead Heath above the level of the Thames! Thus the sound is softened and rises and falls like the surge of the sea on a distant rocky shore.

After the first shock of the immensity of the drop the visitor's attention is drawn inevitably to the gorge. Thickly-wooded hills rising well above the plateau press in on either side until they melt away in the dim distance. Nothing but forest, but such forest, and with light and shade playing on the varied hues of the foliage, this gorge forms a wonderful picture of tropical growth from a unique vantage-point of view. In the centre of the gorge below one's feet is a boiling basin, and beyond the apparently dry rocky bed of the river with an occasional pool. The river forces its way for some miles, out of sight and far below the huge rocks piled helter-skelter in the bottom of the gorge.

On the side the fall is approached—the left bank of the river—the plateau has been carved out in a rough semi-circle, so that by scrambling about half a mile through the forest a point can be gained almost facing the middle of the fall. Here one can sit on the edge of the precipice in comfort in the shade and see the full drop to the pool beneath, at a distance, I should say, of about one-third of a mile from the falling water. Sometimes the fall is hidden by the mist rising from below for days together, but the view generally clears between 10 a.m. and 3 p.m. I have travelled a fair amount, and never have I seen any sight approaching this in beauty. From this position the sensation is of being below the top of the fall, but this is deceptive, as is realised when it is noticed that the river is visible for the whole of the long reach above the fall. The setting is perfect; the forest is untouched; in the distance the highlands and some of the mountains barring the way to Roraima are visible; the placid river glides towards the edge and the amber-coloured water curves over, whitens, and quickly breaks up again and again into arrow-headed gauze-like points which seem to descend slowly and dissipate into vapour before the boiling pool beneath is reached. At the sides it can be dimly seen that there is a great cavern behind the falling water, in which each night thousands of swifts take their rest. The photographic slide I shall show you gives but slight idea of the reality. Colour and movement are lost, and it is only to those who have been there—like our Chairman, who was the first European to visit the fall, and the first to climb Roraima—that a photograph can recall the reality.

Roraima.

Mr. Clementi, the present Government Secretary, has proved that the quickest and easiest way to Mount Roraima is *viâ* the Kaieteur Fall and a day's journey up the river to Holmi and thence overland.

Like Kaieteur, Roraima is unique. It is a flap-topped mountain over 8,000 ft. high, its sides rising some 5,000 ft. above the surrounding country, the top 2,000 ft. being a perpendicular cliff. It was long thought to be inaccessible until Sir Everard im Thurn found a way up along a narrow ledge. Mrs. Clementi accompanied her husband to the summit in 1916, and is the first woman to make the ascent. The journey beyond Kaieteur, after the first day on foot, is at an elevation of over 2,000 ft., and a cooler and more pleasant atmosphere is soon reached. The route is largely through savannah country.

Fish.

The rivers of Guiana are full of edible fish of excellent quality. The chief are the lowlow, haimara, paku, arawana, and arapaima. They are all as food fully equal to good sea fish. The arawana, still only procured by shooting with a bow and arrow, is excellent. I spent one afternoon in a canoe with two Indians, who thus secured four fish averaging about 5 lb. weight. To do this they had over twenty shots. The arrow has a long shaft; on a hit being made the fish dashes off, from the shallow where it has been sunning itself, into deep water. The shaft soon bobs up and is followed. When within reach a violent thrust downward is made to drive the barb well in. When again grasped the fish can be lifted out.

The arapaima is the great food fish of the Amazon, and is rarely found in the Colony outside the mouth of the Rupununi. In that river it is plentiful, as the Indians prefer the smaller and more delicately flavoured arawana, haimara, etc. The arapaima reaches the tremendous size of over 400 lb. It is caught with heavy lines like those used in sea-fishing, but I had an extraordinary afternoon's rod-fishing on my trip to the Brazilian boundary in connexion with the proposed hinterland railway. We had two tarpon rods between three of us—my aide-de-camp, Mr. Bland, the railway engineer, and myself—and we landed seven fish, one weighing just 200 lb., and the seven just over half a ton. With heavy tarpon rods and lines each fish took on an average twenty minutes to land. Fortunately for my reputation I had a camera with me, and photographs of the catch accompanied an article I sent to the *Field* on the subject. On the following day I caught a 75 lb. fish with a salmon rod in about three-quarters of an hour.

The presence of arapaima in the Rupununi and of a very vicious little biting flyfly, one of the pests of the Amazon, are held to be proofs that once the waters of the Rupununi valley drained into that river. Even now the height of the divide between the sea and the Amazon valley is only some 250 ft., and in the wet season the waters of the two river systems approach within half a mile of each other, and Indians drag their canoes across the watershed. If ever the middle Amazon is to be given a route from Manaos, more than a thousand miles shorter than the river route to the United States and Canada, surely it will be over this low watershed to Georgetown. If the line is constructed to Manaos its extension to meet the southern railway systems of Brazil and the Argentine can only be a question of time. The Takatu, on the Brazilian boundary, runs into the Rio Branco, one of the chief tributaries of the Amazon, joining that river near Manaos.

The British Guiana section, if taken from Georgetown to the junction of the Ireng with the Takatu, to which point launches easily ascend, would be some 340 miles. Its construction presents no engineering difficulties, and the cost of a metre-gauge line was estimated by Mr. Bland at only £3,500 a mile. Mr. Buck, the Colonial Director of Public Works, has recently investigated the problem afresh, and recommends a slight variation of the route at Georgetown end, but confirms Mr. Bland's estimate of mileage cost.

I will not here discuss the relative advantages of the two routes beyond remarking that by Mr. Buck's route the distance to the Takutu is increased by twenty-six miles, a very serious consideration as traffic increases, and that Wismar, the probable headquarters of a great bauxite industry, would be left without any other communication with Georgetown than the lengthy river route.

Mr. Nunan, the present Attorney-General of British Guiana, had done much to boom this attractive railway project before my arrival in the Colony, and succeeded in raising great enthusiasm on the subject. Many of the leading men see in this line, without the Manaos extension, a solution of the problem of the Colony's development. I agree with them, and I had hoped to return to England in August, 1914, to press the subject on Mr. Harcourt's attention. I knew he realised its importance, and it would have been fitting that he, one of whose distant ancestors received a grant of the country from James I., and twice attempted to take possession of his property, should be the Minister finally to render the development of its rich interior possible.

The question of financing its construction, however, bristles with difficulties. In the Colony there is much divergence of opinion. The planters of the coast fear the loss of their labour, and urge that the scheme must be accompanied by a costly supplementary one for the introduction of many thousands of settlers. Another section is against construction by Government, refusing to see that it is a project impossible for private enterprise as there is no prospect of paying even working expenses for at least ten years. These people are misled by concession hunters, inexperienced and over-sanguine, to take a charitable view of their promises, who offer to construct the line on easy terms without having the remotest chance of finding capitalists to finance their proposals. The line, if built, must be built with Government money. The Colony cannot afford to carry out the work.

Here seems to me a project eminently worthy of the attention of the Empire Resources Development Committee, not, however, with a view to further development at the expense and for the benefit of the Mother Country, except indirectly. Where would Britain be without her oversea possessions? Taking the tropical Colonies alone, it would be instructive to calculate how many millions are annually poured into the Imperial Exchequer as income-tax, now swollen further by excess profits duty, on receipts by her citizens from their oversea properties, and, on their decease, by death duties thereon. Is it too much that in return the Mother Country should advance, as in the case of the Uganda railway, the means of giving the people, both of the Colony and of the United Kingdom, a chance of proving their ability to take advantage of the opportunities so offered?

Until Mr. Chamberlain ruled at the Colonial Office our West African Colonies were in a much worse state of stagnation than British Guiana. Under his guiding hand, and with financial help from the Treasury, railways began to be pushed up from the coast in each of our West African possessions, with the result that nowhere is there more rapid progress to be seen than in those possessions. Without the progress so ensured we should now be without urgently needed vegetable fats, without our chief source of cocoa supply, and without the troops that have borne the brunt of the fighting in sub-

duing Togoland, the Kameruns, and German East Africa.

Within ten years of the completion of a railway to the savannahs in the interior the cattle traffic should alone be sufficient to cover working expenditure. But great development in mining, the timber trade, and in the exploitation of other forest products may be looked for, as well as the beginnings of agriculture, nor is it likely that with a railway on the Takutu the Brazilians could long resist extending it to Manaos, or at least to a point on the Rio Branco, and thus secure the immense advantage of a direct route to the North Atlantic at Georgetown. With such an extension there would be no further anxiety regarding the financial prospects of the line.

The inhabitants of British Guiana boast of their loyalty. There are many who recall with delight the visit of His Majesty when a midshipman on the "Bacchante." The visits of Her Highness Princess Marie Louise in 1913 and 1914 were made occasions of great demonstrations of loyalty and affection to the Crown and Royal Family. When the war broke out the Colony hastened to present offerings of sugar and rice. Large sums, too, were collected and transmitted to the Prince of Wales's and the Red Cross funds. Collections were made for aircraft, many consignments of made clothing sent to Queen Mary's Needlework Guild, and subscriptions collected for many other of the numerous funds in connexion with the war. Many men went home or to Canada and joined the forces being raised, and British Guiana has sent her contingents, raised locally, to serve in the British West India Regiment.

The war happens to have brought great prosperity to the Colony by raising the price of its staple products, but it has also brought sorrow to many homes there, for the youth of the Colony have taken, and are taking, their part in the great struggle for freedom.

DISCUSSION.

The Chairman (Sir Everard im Thurn) said he had listened to the paper with the greatest interest. As a matter of fact, it probably was even more interesting to him than to anyone else present, because it carried him back into the forests of Guiana, where he spent twenty years of his life, and he could vouch for the accuracy of nearly everything the author had said about the interior of the Colony. His knowledge of the coast land was not as great as his knowledge of the interior, but he took it that the main object of the paper was to call attention to the development of the interior. From early Dutch times down to the present day the coast lands had been adequately developed, and attention must be turned in the future to the interior. Sir Walter Raleigh, rather more than 300 years ago, dreamed of the rich empire of Guiana, and Sir Walter Egerton, who had recently been wandering over the savannahs, believed that by proper development that dream could be made to come true, and the interior of Guiana be made a valuable asset to the Empire. The task, no doubt, would be a difficult one. It was the old story of digging for buried treasure. Guiana could not be developed by those who occasionally went there as visitors, even if they scratched the surface and dug up the gold, diamonds, balata, and other natural produce. The whole scheme must be thoroughly worked out; in fact, the land must be dug as in the old stories of digging for buried treasure, and only then would the treasures be obtained that were really there. That was a very serious and difficult undertaking, and he thought the author was right in saying it must be undertaken as an Imperial task. The resources of the Colony itself were probably not adequate to develop the hinterland properly, but when the war was over, and the Empire again had time to think about the development of its distant possessions, then British Guiana might be developed by some system of introducing free labour—East Indian, Chinese, or from other countries—and a proper system of land tenure. That system would be difficult in some ways in Guiana, owing to the uncertainty about the rights of the Indians in the land, but that difficulty could be overcome. Not only was population needed, but adequate systems of communication. The rivers only went through certain parts of the Colony, and a railway was required to connect one river with another, from the coast to the Brazilian frontier, in much the same way as the author had indicated. During the war, however, and probably for a long time afterwards—for the Empire would have a great deal to do in other ways—he was afraid the development of the interior of British Guiana would have to be postponed. There was one point in the paper that he wished to correct for the sake of historical accuracy. The author had given him the credit of being the first European to visit the Kaieteur Waterfall, but that was not the case. The Kaieteur was discovered by Mr. Barrington Brown about the year 1872, and it was Mr. Barrington Brown's book, "Canoe and Camp Life in British Guiana," notices of which appeared in the *Saturday Review* in 1877, that was one cause of his going out to Guiana. About two years after the Kaieteur was discovered, Sir George Young, who was in Guiana at the time in connection with the inquiry into the East Indian labour there; Colonel Webber, who was in command of the troops then stationed in Guiana; and a certain well-known planter, John Bascombe, went to the Kaieteur and anteceded his own visit, which was in 1878. Therefore, although he could claim the credit of having been the first to see the top of Roraima, he could not claim the credit of being the first European to see the Kaieteur.

Mr. C. Sandbach Parker, C.B.E., said that, as one who had lived in British Guiana for some years and had been identified with the Colony for the whole of his business life, he had listened to the paper with the greatest possible interest. About six years ago, when he returned from his last visit to British Guiana, at the request of the Royal Colonial Institute, he gave an address on the development of British Guiana—a development which he thought all those interested in the Colony desired to see, and he hoped would be brought about within his lifetime. It was a totally different proposition to build a railway to the Brazilian frontier from what it was to build a railway in any other country in the world, simply because of the scarcity of population. With a huge country of 90,000 square miles, containing a population of only 300,000, largely employed in existing industries, it was obvious that no labour could be spared for the development of the interior of the Colony. The railway should be gradually built with labour from outside the Colony, and in the paper to which he had referred he showed how very desirable it was that an effort should be made to induce immigration into the Colony in the form of colonising families. Two types of settlers were required—people who were prepared to work for wages and people who would colonise the interior, and, as the railway proceeded, take up the various industries which could be best undertaken in family life. The photographs the author had shown of the magnificent savannahs and the Kaieteur Falls and the riches of the interior of British Guiana inspired one with the greatest possible desire to see a practical scheme carried out for opening up the interior. Indians were required for labour in the agricultural industry, and his suggestion was that the colonising families should be obtained from the same sources from which they were obtained in Brazil; but in these days one would be very anxious to see British Guiana populated by British people. That was one of the lessons of the war—we desired to see our own countries populated by our own people, and, therefore, one would think twice before inviting large colonies of aliens to come and settle in British Guiana. The future prosperity of the Colony depended very much upon what the Imperial Government was going to do. The prosperity of British Guiana had been great during the war, and might continue so for some years afterwards; but if that prosperity was going to be built up permanently there must be security for capital and industry. That had never been the case in the past, but it would have to be so in the future. It was easy enough to formulate schemes for the development of new industries, but unless the people who took up those new industries were given some security, they would not come to the Colony in large numbers and make a success of the industries, and so build up the prosperity of the country. Although he had been interested mainly in the sugar industry, he was very anxious to see the other riches of British Guiana developed. That development must be carried out with prudence, and the proper steps must be taken to ensure the success of the industries.

Mr. Edward R. Davson said it was very gratifying to find that the author, having laid down the reins of office, was still sufficiently interested in British Guiana to write such an admirable paper about it, the study of which he was sure would be of great benefit to the Colony. He quite agreed that a railway into the interior would be an excellent thing for opening up the Colony, a railway not so much in the direction of a trans-continental trunk line, as to the advantages of which he was still a little sceptical, but one primarily for the development of the resources of British Guiana itself. There were two points that had to be considered in connection with any railway, or any development of the Colony, whether in the hinterland or on the coast, namely, money and labour. The revenue had been increasing considerably in the last few years, but at the same time the cost of administration had been rising, and there was also the apparently never-ending drain upon the resources of the Colony in the maintenance of its coast defences. It was the great tragedy of the country that a large part of the money collected by taxation was being spent in such a manner that no return could be obtained from it. Even more important than that was the question of labour. It was deplorable that at the present time, when the Mother Country was in need of a great variety of products which could be grown in British Guiana, they could not be cultivated because of the scarcity of labour. Even with regard to rubber there were grave doubts whether, with the present cost of labour, British Guiana could ever compete with the East. If a new industry was started in the Colony it simply drew people away from an old industry. The great problem of the country was the problem of labour; if that could be solved then he believed the development of British Guiana would automatically follow.

Sir Sydney Olivier, K.C.M.G., C.B., in proposing a vote of thanks to the author, said he himself had been connected with the Colonies most of his life, and had passed through that curious experience of a colonial Governor, who, serving in places where obviously very much more might be done both for the Colony itself and for the Empire, thought and schemed to get things done, which seemed so reasonable and in some respects so simple, and yet for lack of ways and means had to see them remain undone. All present would be very grateful to the author for reading the paper, which served to remind them of the existence of places like British Guiana and the West Indies, which he hoped would be much more in the thoughts of the people in this country after the war than they were before. He was rather struck by the passage in the paper where the author spoke of the bauxite industry, which it was apparently considered quite natural should be developed by an

American company. He had lived in Jamaica and had seen a great deal of money made there by Americans instead of British people. British capitalists had been extremely shy of investments in the West Indies and of any kind of progressive work there, because from their experience in the sugar industry they had felt they could not be reasonably sure of making a profit. Speaking as a Free Trader, he thought the British Isles had treated the West Indies very scurvily. It would have been very much better for them at the present time if they had treated the British West Indies in a more just and patriotic manner, because then the sugar production of those colonies, and consequently our own domestic supply, would have been in a much more healthy condition than it was at present. It was most important that those who knew something about the outlying parts of the Empire should attract all the public attention they could to those colonies. Although the photographs the author had shown and the descriptions he had given conveyed an idea of the beauty of British Guiana, no pictures could reproduce the effect of the extraordinary spiritual exaltation one obtained from the early morning aspect of such upland tropical forest scenes as those referred to in the paper. If in time the uplands of British Guiana could be made a resort for Europeans and a place for European colonisation, it would add very greatly to the sum of human happiness, and he thanked the author for having indicated some of the ways in which that could be done.

Mr. W. A. Wolseley, in seconding the resolution, said that as the labour supply of the Colony had been specially referred to, he would like to point out the following fact: the success that had attended the production of sugar in British Guiana, and also of rice, in recent years, had been due in a large measure to the introduction of East Indian immigrants under indenture. Many of these immigrants were not agricultural labourers at all, but were taught and trained to be so during their period of indenture. The result was a body of labourers most efficient and, owing to their own qualities, as pleasing and satisfactory as any employer could desire. He, therefore, greatly regretted that immigration under indenture to British Guiana had ceased.

The resolution was carried unanimously.

Sir Walter Egerton, in reply, said, in reading such a long paper and touching on such contentious subjects, he had been peculiarly fortunate to have evoked such mild criticism. The question of a hinterland railway in British Guiana was a very contentious subject. Naturally the planters on the coast dreaded their labour being attracted to the interior, and he agreed with Mr. Sandbach Parker that when that railway was built it should be built with newly imported labour. He did not think, however, the planters need fear that if the railway was built there would be a sudden rush to the interior. The people who lived in British Guiana had grown accustomed to their semi-amphibious life there, and probably they would not like living on hills. Most of them had never seen a hill; the highest point one drove over from one end of the coast to another was the top of a bridge traversing one of the canals. The railway, however, could be made to pay without population. There were over 10,000 square miles of savannah country in British Guiana ready to carry a hundred times the cattle that were now there, and a trade in cattle would grow up that would be quite sufficient to pay the working expenses of the railway. A railway of that kind, giving access to fertile country, would be a certain attraction to immigrants from outside the Colony who were not accustomed to live half under water at high tide. British Guiana's past prosperity, its present prosperity, and probably its future prosperity for a long time to come, depended on the sugar industry. He agreed with Sir Sydney Olivier that the country had not been well treated in the matter of its sugar production. Surely after the war this country would adopt the policy of the United States and give some sort of preferential treatment to its colonies, and not allow the produce of foreign lands to be brought to this country to the detriment of lands which had been developed with the capital and labour of its own people. Cuba and Honolulu had enjoyed wonderful prosperity through being linked to the United States. Had the granting of preferential treatment to sugar imported from those countries injured the people of the United States? The answer was that they had tried it now for a long time and they still persisted in the policy, although there had been proposals brought forward for its abolition.

Mr. Alan S. Cole, C.B., expressed the thanks of the Council to Sir Everard im Thurn for presiding, and the meeting terminated.

CHICLE INDUSTRY OF GUATEMALA.

The chicle industry of Guatemala is confined almost exclusively to the Peten—that inaccessible north country of the Republic bordering on Mexico and British Honduras. Apart from the archæologists from Harvard and Yale Universities, who find in the ruins of Peten a remote past of increasing interest, Peten remains virtually unknown except to the workers in the chicle and mahogany districts.

The country is reputed to be of dense tropical undergrowth, swampy, the climate very unhealthy, but a territory rich in undeveloped resources. Concessions for constructing a railway in the Peten have been sought from the Government, but none has yet been granted.

It is estimated that the investment in the Peten country in the chicle industry aggregates about £50,000. No one is permitted to gather chicle without a Government concession. Four concessions of this nature have been granted, and they cover the most desirable chicle lands of the region. Good chicle land is said to be worth from £300 to £400 per caballeria of 33⅓ acres, but nearly all the land is owned by the Government of Guatemala, the owners of concessions enjoying only the right to remove the chicle. Chicle grows wild, and steps have never been taken either to cultivate the tree or to provide for reforesting the land with it.

The chicle resources of the Peten country are declared to be practically inexhaustible. It would appear from the statements of concessionaires that no formal estimate of the chicle in the Peten region has been made; and that, in many instances, holders of concessions do not know just what amount of chicle grows on their land. The tree, which bears a luscious brown fruit, is found chiefly at altitudes ranging from 500 to 2,000 feet. In some districts twenty-five to fifty trees are found per acre, while in other regions the trees are greatly scattered.

From a report by the United States Consul at Guatemala City, it appears that chicle trees are boxed and cupped in a manner similar to the "boxing" of pine trees for the extraction of turpentine or resin. A large tree will yield as much as 100 lb. of the crude gum, and smaller and younger trees less in proportion. The trees are boxed on an average three times in as many years. The gum is boiled in large iron pots, from which it is poured into wooden boxes with a capacity of 80 lb. each. The gum hardens in these boxes, and it is carried in this form to the shipping seaport, where the boxes are removed and the chicle packed in sacks for export.

Native labour is employed by the chicle producers, and the workmen are said to be among the highest-paid labourers of the Republic, receiving at the rate of £2 for each quintal of chicle they gather. At this rate, an industrious workman earns from £5 to £6 per month.

Flores is the principal Guatemalan market for assembling chicle; the bulk of the product is shipped for export *viâ* Belize, British Honduras. In Flores crude chicle is worth £3 to £4 per quintal of 101·4 lb. Most of the chicle is carried from Flores by muleback to El Coyo, and thence shipped *viâ* the Belize River to Belize, British Honduras. By the time it reaches the seaboard the chicle has appreciated in value from £6 to £8 per quintal.

Prior to the European war a part of the chicle movement was to England, but at this time practically the entire product goes to the United States, where it meets with a ready market. In the year 1915 a total of 7,238 quintals of chicle, valued at £48,200, was exported *viâ* the frontier custom-house of Peten; for the year 1916 the total chicle exportation was 4,071 quintals, valued at £27,100.

GENERAL NOTES.

British Scientific Products Exhibition.—The British Science Guild is organising a comprehensive exhibition of Products and Appliances of scientific and industrial interest which, prior to the war, were obtained chiefly from enemy countries but are now produced in the United Kingdom. The exhibition, which will be held at King's College from about the first week in August until the first week in September, will show in the first place products chiefly imported from Germany before the war, but now made in this country; but it will also illustrate the remarkable developments that have taken place generally in our scientific industries. In many of these, as a matter of fact, Great Britain always excelled, and it is only our national quality of self-depreciation which has prevented the public from appreciating the fact that we were able to export to Germany apparatus and products embodying the highest scientific knowledge and technical skill. The exhibits will include chemical products, thermal, electrical and optical appliances, glass, quartz, and refractory materials; photographic apparatus and material; surgical and medical appliances; and papers and textile products. It is believed that the effect of the exhibition will be to have a most stimulating influence upon scientific and industrial research; and the exhibits, and the demonstrations and lectures that will be given in order to explain them, will undoubtedly bring home to manufacturers, as well as to the general public, the great and growing part that science plays in industry. Further particulars may be obtained from the Organising Secretary, 82, Victoria Street, London, S.W. 1.

Paraguayan Handmade Lace.—Among the cottage industries of Paraguay is the manufacture of a lace called "nanduti" (from the Guaranian word meaning web). The articles produced, which are all made by hand, include parasol covers, handkerchiefs, doylies, boleros, mantillas, table mats, shawls, edging and insertion. The articles most popular with the foreigners in Paraguay are parasol covers, mantillas, doylies, handkerchiefs and mats, these being made of silk or very fine cotton thread. These laces, reports the United States Consul at Asuncion, appear to be superior in quality and design to similar laces made in the Canary Islands and Mexico. A handkerchief that requires from six to eight weeks to make sells in Asuncion for 100 to 150 Paraguayan pesos, and a parasol cover that takes a year to make sells for 600 to 1200 pesos, the Paraguayan peso at the date of the report being worth about 1½*d*. The lace is usually sold by peddling it from house to house, and, so far as is known, it has never been exported to any important degree. However, the leading export houses in Asuncion might be in a position to handle the trade should a foreign demand for the lace develop.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd. York House, Portugal St., W.C

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

MEETINGS FOR THE ENSUING WEEK.

Monday, June 17...Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Rev. Professor D. S. Margoliouth, "The Future of Education."

Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 6.30 p.m. Mr. A. R. Ling, "The Storage of Hops."

Tuesday, June 18...Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Mr. K. Yamasaki, "Recent Economic Developments in Japan in their relation to her Trade with the United Kingdom."

Wednesday, June 19...Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Professor E. W. Hope, "The Influence of a Ministry of Health on Local Organisation and Administration."

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Dr. S. Chapman, "The Lunar Atmospheric Tide at Greenwich, 1854-1917." 2. Mr. M. Christy, "On the Audibility of the Gunfire on the Continent at Chignal St. James, near Chelmsford, during 1917." 3. Mr. F. J. W. Whipple, "Seasonal Variation in the Audibility of Distant Gunfire."

Microscopical Society, 20, Hanover-square, W., 8 p.m. 1. Professor B. Moore, "Photo-synthetic Processes." 2. Dr. E. Penard, "A New Type of Infusorian, Arachnidiopsis paradoxa." 3. Messrs. E. Heron-Allen and A. Earland, "Diatom Ooze from Deep Antarctic Waters." 4. Mr. J. M. Offord, "Exhibition of Gnats and Gnat larvæ."

Geological Society, Burlington House, W., 5.30 p.m.

Thursday, June 20...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Hon. Sir Dinshaw E. Wacha, "Indian Cotton and the Cotton-Mill Industry."

Linnean Society, Burlington House, W., 5 p.m.

Chemical Society, Burlington House, W., 8 p.m.

Friday, June 21...Chadwick Public Lecture, Mansion House, E.C., 5 p.m. Professor D. W. Thompson, "Our Fisheries and the Food Supply. Lecture I.—The Catch by Line and Trawl."

Journal of the Royal Society of Arts.

No. 3,421. VOL. LXVI.

FRIDAY, JUNE 14, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

THURSDAY, JUNE 20th, at 4.30 p.m. (Indian Section.) A paper by the HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, on "Indian Cotton and the Cotton-Mill Industry" will be read by SIR CHARLES ARMSTRONG, late Chairman, Bombay Chamber of Commerce. The RIGHT HON. E. S. MONTAGU, M.P., Secretary of State for India, will preside.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Sixty-fourth Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new Fellows, will be held, in accordance with the By-Laws, on Wednesday, June 26th, at 4 p.m.

(By order of the Council),

GEORGE KENNETH MENZIES, *Secretary.*

SWINEY PRIZE.

The Council have to give notice that the next award of the Swiney prize will be in January, 1919, the seventy-fifth anniversary of the testator's death. Dr. Swiney died in 1844, and in his will he left the sum of £5,000 Consols to the Society of Arts, for the purpose of presenting a prize, on every fifth anniversary of his death, to the author of the best published work on Jurisprudence. The prize is a cup, value £100, and money to the same amount; the award is made jointly by the Royal Society of Arts and the Royal College of Physicians.

In accordance with the arrangement with the Royal College of Physicians, the award next year will be for Medical Jurisprudence.

Any person desiring to submit a work in competition, or to recommend any work for the consideration of the judges, should do so by letter, addressed to the Secretary of the Society.

The following is the list of the recipients:—

1849. J. A. Paris, M.D., and J. Fonblanque, for their work, "Medical Jurisprudence."

1854. Leone Levi, for his work, "The Commercial Law of the World."

1859. Dr. Alfred Swayne Taylor, F.R.S., for his work, "Medical Jurisprudence."

1864. Henry Sumner Maine (afterwards K.C.B.), D.C.L., Member of the Legislative Council of India, for his work, "Ancient Law."

1869. William Augustus Guy, M.D., for his work, "Principles of Forensic Medicine."

1874. The Right Hon. Sir Robert Joseph Phillimore, D.C.L., for his work, "Commentaries on International Law."

1879. Dr. Norman Cheevers, for his work, "Manual of Medical Jurisprudence of India."

1884. Sheldon Amos, M.A., for his work, "A Systematic View of the Science of Jurisprudence."

1889. Dr. Charles Meymott Tidy, F.C.S., for his work, "Legal Medicine."

1894. Thomas Erskine Holland, D.C.L., for his work, "The Elements of Jurisprudence."

1899. Dr. J. Dixon Mann, F.R.C.P., for his work, "Forensic Medicine and Toxicology."

1904. Sir Frederick Pollock, Bart., and Professor F. W. Maitland, for their work, "The History of English Law before Edward the First."

1909. Dr. Charles Mercier, for his work, "Criminal Responsibility."

1914. John W. Salmond, K.C., for his work, "Jurisprudence."

PROCEEDINGS OF THE SOCIETY.

NINETEENTH ORDINARY MEETING.

Wednesday, May 1st, 1918; The RIGHT HON. LORD BALFOUR OF BURLEIGH, K.T., G.C.M.G., G.C.V.O., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Cleminson, H. M., London.
Dutton, Reginald John Garfield, Skegness.
Howell, Alderman Thomas H., Newport, Monmouth.
Librarian, National Library of Ireland (Department of Agriculture and Technical Instruction), Dublin.

Martineau, William, Wallingford.
Oury, Libert, London.
Taylor, W. Howson, West Smethwick.

The following candidates were balloted for and duly elected Fellows of the Society :—

Burley, Sydney Waterlow, Sittingbourne, Kent.
Kendrick, A. F., London.
Lawrey, William, Penzance.
Newman, James Harold, London.
Oliver, William Grant, L.D.S., London.

The paper read was—

SUGAR FROM SEVERAL POINTS OF VIEW.*

By George Martineau, C.B.

Dr. H. C. Prinsen Geerligs, in his fine work on "The World's Cane Sugar Industry, Past and Present," gives a long and interesting account of the early history of sugar. He goes back to Hindu mythology. A certain famous hermit, once upon a time, was desired by an Indian prince to procure for him permission to be translated to heaven during his lifetime. This was refused, but the hermit kindly furnished for him a temporary paradise on earth. This seems to have included, among its many delights, the sugar cane. After the destruction of this paradise, the sugar cane was spread all over the world as a memorial of the famous hermit. No date is mentioned.

When we emerge from these pre-historic times we again meet with real sugar, for the first time, in India. It is called "gur" in India now, and that seems to have been its name from very early days.

In the seventh century, A.D., the fact is on record that a Chinese Emperor sent people to India to learn the art of sugar manufacture. The natives in India at the present time are content to produce "gur" by boiling down the juice from the cane till it solidifies. But it appears that even in that early period the Arabs, when they got hold of the sugar cane, learned to purify the raw sugar by re-crystallisation and to produce a great variety of sweetmeats.

In the thirteenth century travellers reported the existence of many sugar factories in China. Then we hear of the Arabs taking the sugar cane to Sicily, and thence to Africa. Thus it spread all round the coasts and islands of the Mediterranean. The Crusaders found extensive sugar plantations in many parts. Spain boasted of a flourishing sugar industry even in the twelfth century. From China the sugar cane found its way to the Indian Ocean, to Siam, the Philippines, Formosa, and Japan. But in those days it was only in China and the countries round the Mediterranean that a real sugar industry existed. The Crusaders took a great interest in the cultivation of the sugar cane, and founded many important centres of the industry.

When these early industries produced more than they consumed, a trade in sugar sprang up. The Crusaders, when they got home, began to import it, and a brisk trade started between the Italian ports and Northern Europe. It is curious to note that in these early days the traffic was in refined, not raw sugar. This is easily explained by the fact that the art of sugar-refining had not yet reached to Northern Europe. It was actually loaf sugar that the Crusaders and others imported from the Mediterranean ports. We hear of Damascus and Tripoli becoming great sugar-refining centres in the fourteenth century.

Then, alas! in the fifteenth century the Turks began to overrun these countries, and the sugar industry had a bad time; in fact, as Dr. Prinsen Geerligs says, "the once flourishing sugar industry of the Mediterranean was condemned to extinction." But, in the meantime, the Portuguese took the sugar cane to Madeira, the Azores, the Cape de Verde Islands, and the Gulf of Guinea. Spain colonised the Canary Islands. In all these places a new sugar industry spran up and flourished, especially with the help of slave labour. Then came America. Spain, Portugal, Holland, Great Britain and France colonised a vast territory, and sugar, instead of being a fancy luxury, soon became an article of common consumption. Fertile land, a favourable climate, and cheap labour formed the basis of the great sugar industries of the West. First Brazil, then the West India Islands, English, French, Spanish, and Dutch, then other countries on the mainland of America, Surinam, Demerara, Berbice, and finally Peru, Argentina, Chile, Mexico, and Louisiana. The competition

* This paper is written to prove, from the history of sugar during the last sixty years :—

1. That nascent industries can be encouraged, research stimulated, and efficiency created, by a rational, well regulated, but moderate stimulus.

2. That preferential treatment in home markets is the best, perhaps the only, way to give real confidence to capital; and that with that confidence, coupled, of course, with favourable natural conditions, British industries will flourish, and may even become capable of furnishing the whole consumption of the Empire.

3. That the dumping of commodities below cost price is a fatal injury to the consumer.

from these new countries soon extinguished the little industry in Madeira, the Cape de Verde, and the Canary Isles.

France introduced sugar cane into Mauritius and Réunion, which soon began to export sugar to Europe. Early in the eighteenth century the Dutch East India Company, which had been importing sugar from Formosa, Bengal, and Siam, introduced the sugar cane into their Island of Java; but the wonderful success of that most remarkable of all cane-sugar industries did not take place till long afterwards.

Then, at the birth of the nineteenth century, came the great war between France and Great Britain, and the cane-sugar industry had a bad time. Naval engagements in West Indian waters, the sinking of sugar cargoes, the capture of merchant ships, not only from the West but also from the East, and other blows dealt by France at British trade, did not conduce to the development of the cane-sugar industry. Finally came Napoleon's "continental system."

I am much obliged to Dr. Prinsen Geerligs for enabling me to give this brief sketch of the early history of cane sugar, and can now go forward to my own personal experiences from 1856 to the present day.

In 1856 our industry of sugar-refining was in a flourishing state. Practically all the loaf sugar consumed in this country was produced in the East End of London, where about twenty refineries, each doing a few hundred tons a week, were very busy, giving work and wages to the surrounding neighbourhood, and keeping the London Docks fully occupied with the thousands of hogsheads of West India sugar which were annually imported. That was the sugar which we principally used, helped out with sugar from Mauritius, British India, the foreign West Indies, and the foreign East Indies. The total, in 1856, was 384,000 tons of raw cane sugar, to which must be added 9,000 tons of foreign refined sugar and 4,000 tons of raw beetroot sugar. That gives a total consumption of 397,000 tons. The remarkable point is that of the 384,000 tons of raw cane sugar 285,000 tons, 70 per cent., came from our sugar-producing British Possessions, East and West, but especially West. Those were good days, not only for British sugar-refining but also for the British West Indian Colonies and Mauritius. It will be interesting, for a moment, to look at the kind of sugar which the world produced in those days, and especially at our largest contributors, the British West Indies.

The British West Indian sugar of sixty years ago was an excellent class of raw sugar, so good, in fact, that a considerable portion of it was pure enough to go direct into consumption, and it is with regret that those who were intimately acquainted with it view its impending abolition. It was well made, with great skill and care, a skill which has probably by this time nearly died out. It was a primitive process, but much superior to other primitive processes of those days, some of which, unfortunately, still survive. It was called "muscovado sugar," and was produced by a simple process, giving a good result when well done, but very different to present requirements.

At the date with which we are now dealing the world produced about 1,200,000 tons of cane sugar and 250,000 tons of European beetroot sugar—total 1,450,000 tons. The cane-sugar producing countries of those days, mentioned in the order of their importance, were Cuba, Java, Mauritius, the British West Indies (including British Guiana), Brazil, Porto Rico, Manilla (the name in those days for sugar from the Philippine Islands), Réunion, Louisiana, and the French West Indian Islands of Martinique and Guadaloupe. The finest raw sugar came from Java, Mauritius, the French West Indies, Réunion, and Louisiana. Cuba made a semi-refined raw sugar called Havana, but the bulk of its production was a muscovado sugar, very inferior to the British variety. Porto Rico, on the contrary, produced a very fine muscovado sugar, quite fit for direct consumption. The sugars from Brazil, Manilla, and British India, were very low brown impure varieties, requiring a great deal of refining. The British refiners were experts with that class of sugar, while the foreign refiners, in France and Holland, preferred the easier work —mere child's play—with a raw material of a much higher grade, in fact, almost pure.

The British sugar-refining industry in 1856 was not confined to London, though London produced practically the whole of the loaf sugar which we consumed. Bristol was a very old-established centre of the industry. The great house of Finzel, then the largest refinery in the country, was celebrated for its large grained crystallised sugar, and was the first to use the newly invented centrifugal machine. Liverpool also was a large contributor to our refined-sugar production. Ships from Brazil were constantly arriving in the Mersey and bringing, among other things, the low brown sugar from that country. In the Clyde also a new and flourishing

industry of sugar-refining was springing up. It increased with great rapidity, having discovered a new way of producing yellow sugar of very superior colour and quality, a kind popular with the buyers of the cheapest article. The history of the rise and progress of this industry is interesting, as an indication of the vicissitudes through which the sugar-refining industry of this country had to pass between 1887 and 1903.

In 1854 the sugar-refiners of Greenock (and Glasgow) imported 50,000 tons of raw sugar. In 1865 they imported 136,000 tons, and the figure went on increasing rapidly until, for the five years, 1877–81, the average yearly importation was 248,429 tons. This figure held till 1887, when a fall, as rapid as the rise, set in. For the five years, 1887–91, the average yearly imports had fallen to 228,733 tons, for the following five years to 170,373 tons, and for the years, 1897–1900, to 124,874 tons, a lower figure than that from which they started in 1865. Presently we shall see the reason why.

This is the completion of our brief sketch of sugar sixty years ago. Let us turn to another picture—after a violent revolution. The last year of the nineteenth century, 1900, was a record year in the history of sugar. Our consumption had risen from 397,000 tons to 1,624,000 tons—more than four times as much. That is a wonderful fact, but another, far more incredible, comes next, namely, that out of this enormous quantity of sugar consumed in the United Kingdom only a little scrap, 129,000 tons, was produced from the good old sugar cane. Even that small quantity would not have come to us had it not been for two facts—first, that our Colony of Demerara produced a very choice kind of yellow crystallised sugar which a few intelligent connoisseurs insisted upon having; and, secondly, because two of our sugar-refining firms stuck to cane sugar, hoping to obtain a fancy price for their refined sugar. We hope they did.

But there is one more almost equally incredible fact to be revealed. The world's production (not including the imaginary figure for British India, which now confuses our statistics) had increased from 1,450,000 tons to 8,291,800 tons—nearly six times as much. Now comes the most wonderful fact of all. Of this quantity, only 2,880,900 tons was the product of the sugar cane—less than 35 per cent.; in other words, nearly two-thirds of the world's production of sugar came from the beetroot fields of Northern Europe and, to a small extent, from the beetroot fields of the United States. These facts are worth looking into, in order to discover causes for such startling effects. I could spend several hours in explanation—all of it interesting—but we must be brief.

There is no need to go into the history of the origin of beetroot sugar here; suffice it to say that Napoleon Bonaparte had something to do with it, and also the King of Prussia. I said that in 1856 Europe produced about 250,000 tons of beetroot sugar. That was doubled in ten years, and in five years more the production exceeded a million tons. Another ten years raised the figure to two millions. This brought cane and beet neck and neck in the race; then beetroot shot ahead to three, four, five, and six million tons.

There are two causes at the bottom of this mystery. Energy, ability, efficiency, and, more than all, persistent research, constituted the first and best cause. But this best cause is not to be had, as a rule, unless you give it a stimulus. Capitalists do not care to risk their money unless they can see very clearly that there is some security for their investment. That is exactly what the European beetroot-sugar industry enjoyed; all except France, who had to languish till 1884. France gave the research most liberally, but she lacked the stimulus.

It was Germany that hit upon the right kind of stimulus. It was a brilliant idea, quite an inspiration, and was carried out with great judgment. The sugar duty was levied—not upon the sugar produced, but upon the roots. This at once stimulated the farmer to produce the richest possible quality of root, and the manufacturer to extract from the root the largest possible quantity of sugar. Great pains were taken to breed an improved variety of sugar-beet. This great research lasted for years, and still goes on. Its success was astounding—incredible. At the beginning the sugar-beet contained less than 6 per cent. of sugar. In France it continued to contain less than 6 per cent. of sugar until the stimulus was applied in 1884 to save the life of the industry. But in Germany the roots went on, year after year, increasing in richness until, in 1908, the average quantity of sugar actually extracted from the roots for the whole of Germany was 17·63 per cent. I used the word "incredible," and it is the only word to use. The natural quantity of sugar contained in the sugar-beet had been multiplied by three. For the ten years, 1899–1908, the average yield for the whole of Germany

was 15·49 per cent. This shows what can be done by giving a rational and very moderate stimulus. That this wonderful result was caused by the stimulus—plus, of course, great efficiency—is proved by the lamentable fact that poor France, who received no stimulus till 1884, was at that date getting a yield of less than 6 per cent. of sugar, while Germany at the same time was producing 11 per cent. of sugar from the roots as the average for the whole country. France hastened to adopt the German system, but never succeeded in catching it up in the race. The average yield for the ten years, 1899–1908, which, as I have said, was 15·49 per cent. for Germany, was only 12·84 per cent. for France. This is the worst of being "too late." In industry it is fatal. Austria, with a system similar to that of Germany, got a yield of over 15 per cent. for those ten years.

Research was still rampant, and the breeding of the rich roots led to the invention of the diffusion process—another result of the stimulus. This process, now brought to great perfection, practically extracts the whole of the juice, and in a very pure state. In my book on sugar I gave the results of a good German factory in 1908, from which it will be seen that the average quantity of sugar contained in the roots worked by that factory throughout the season was 17·10 per cent., and that the quantity actually extracted was 16·64 per cent. These figures show what can be done when efficiency reigns supreme, and they are also a good illustration of the perfection to which chemical control of a sugar factory can be brought. Everything that happens is known, down to the second place in decimals. France, so long as she worked roots containing less than 6 per cent. of sugar, could not attempt the diffusion process.

Another instance of the valuable results of research is the multiple evaporator, called by the French the "Triple Effet." The French had a considerable share in bringing this invention to a practical success. It has enabled the sugar factory to perform the most important and expensive part of its process—that of evaporating the thin juice till it is thick enough to crystallise in the vacuum pan—with the lowest possible expenditure of fuel. Research is still going on with regard to this part of the process, and has not yet said its last word.

Greatest of all the results was the gradual development of the new method of purifying the juice, called the double carbonatation process. We have no time, on such an occasion as this, to describe processes, but I can safely assert that this must be regarded as one of the greatest of all the results of the researches of the last fifty years in the world of beetroot sugar. It has now found its way to Java, where fine white sugar is being produced in large quantities by means of it. But here again there is no finality, and it is quite possible that a still better process, giving equally good results at less expense and trouble, may eventually take its place. Research is still busy with it.

The great cane-sugar industries of the world did not take a *laissez-faire* view of the subject. They immediately buckled to and set their house in order. They at once adopted the multiple evaporator, and now every modern factory has one, or perhaps several. The diffusion process was tried, but found to have too many drawbacks when applied to cane-sugar production; but they were determined to try to extract if possible nearly the whole of the juice in the cane. Instead of having only one three-roller mill, which squeezes the cane twice, they now have four, placed tandem fashion with travelling bands between, and thus give the cane eight squeezes. They also place two rollers with rough surfaces at the entrance to the first mill, which crack the hard crust of the cane before it enters the mill. With these improvements and "maceration" of the "megass" (the crushed cane) in its transit from mill to mill, they now extract 95 per cent. of the juice, and are ready to fight the beetroot industry. Instead of hundreds of tons, they are turning out thousands from each factory, and thus reducing cost of production. They have, however, their own special difficulties to surmount. Labour is one of the greatest. Here Java is in a favoured position. She has also good soil and climate, great efficiency in management, and a fairly good system of irrigation. The necessity of supplying the cane with sufficient water is vital, and water is not always attainable.

The cost of production depends, to a great extent, on the quantity of canes per acre which can be produced. Java produces more than forty tons as an average for the whole of the island, and can therefore produce sugar at a very low cost, all the factory arrangements being thoroughly efficient. Half of Java's crop of about 1,500,000 tons (rapidly increasing) is now produced in the form of white granulated sugar of high quality, which goes to British India for the benefit of the upper classes. Our Colony

of Mauritius is doing the same, and deserves to succeed after all the cruel troubles she has gone through. White sugar direct from the beetroot juice has been produced for a long time. The present writer recollects seeing one beetroot factory in Germany, as long ago as 1871, turning out good loaf sugar; and at a later date he saw Eugen Langen, the inventor of the cube-sugar process, producing very fine cubes at his factory at Elsdorf direct from the beetroot juice.

This great effort of the cane-sugar industry to compete with beetroot brings us to another striking result of giving industry a stimulus. I have shown how the German stimulus, rationally applied, led to greater efficiency, profound research, and most astounding results. I have compared it with the sadly backward state of the same industry in France, so long as it received no stimulus. And yet I find, if I consult a recent utterance of the *Council* of the Manchester Chamber of Commerce, that industries receiving such a stimulus are bound to become "apathetic and inefficient." Very well, I have given facts of practical experience in flat contradiction to this doctrine—a doctrine, by the way, which the members, as distinguished from the Council, of the Manchester Chamber have now, I am glad to see, repudiated most emphatically.

I will now give more facts of practical experience, this time from the cane-sugar industry, which again will prove conclusively that this doctrine, so glibly repeated as if it were an axiom, is an absolute delusion. The United States of America give preferential treatment in their own markets to sugar produced in their own states, territories, and dependencies. They also gave a slight preference—rather more than half a farthing a pound—to their *protégé*, Cuba. Let us see what has been the result of this preference—absolutely inappreciable to the consumer. Cuba, before the Spanish-American War, just succeeded in producing a million tons of sugar per annum in the years 1894 and 1895. After the American occupation in 1898, and when the unfortunate industry had succeeded in recovering from the devastation of the war, the stimulus of the small preference began to tell. In 1903 Cuba got back to the million ton figure. In 1913 it produced 2,500,000 tons, and last year it would have produced 3,500,000 tons, but, unfortunately, when the sugar was badly wanted, an insurrection broke out in the eastern part of the island, and the actual production was reduced to 3,000,000 tons. This enormous increase was the result of the security capitalists found in the small American preference. Large factories were erected, railways connecting them with the shipping ports were constructed, everything was done in the most up-to-date style, and the only trouble was to get the sugar sold and shipped as soon as possible. The United States markets were glutted during the thickest part of the crop time, and prices went down sometimes more than £2 per ton below the European level. The American consumer actually gained by the preference.

In Cuba at the present time there are many factories that turn out from 10,000 to 20,000 tons of sugar per annum. There are about the same number which turn out from 20,000 to 40,000 tons. There are eight that turn out from 40,000 to 60,000 tons. There are three that turn out from 60,000 to 80,000 tons. There is one that produces between 80,000 and 100,000 tons, and there is one that produces more than 100,000 tons per annum. This is the "apathy and inefficiency" created by giving a preference!

The greatest research now going on in the cane-sugar industry is the breeding of new varieties of cane which shall give more sugar, resist disease, and be suitable for various soils and climates.

I will conclude by giving one more instance of the results of preferential treatment in the home market. We know from recent experience how comfortable it would be if we could produce enough sugar for our own consumption without going to foreign countries for it. The United States are now in that happy position. Since the preference was granted Louisiana has increased her production from 95,000 to 414,000 tons; domestic beetroot from 1,000 to 779,000 tons; Hawaii (the Sandwich Islands) from 12,000 to 602,000 tons; Porto Rico from 50,000 to 400,000 tons; the Philippine Islands from 92,000 to 300,000 tons; and, finally, Cuba from 1,000,000 to 3,500,000 tons. If America had not created this great increase in production by giving a preference to her own family and friends we should at the present moment be suffering—and so would America—from a real sugar famine. Instead of that what do we see when we turn to American statistics for 1915? In that year the consumption of sugar in the United States amounted to the large figure of 4,257,713 tons, every ounce of which, with the purely accidental exception of 23,000 tons, came from her own states, territories and protectorates. This striking fact is entirely the result of giving a

preference. The United States, so far as sugar is concerned, is now independent of the outside world, and is even able to spare us a million tons from Cuba whenever we are short of supplies.

This ends my essay. There is another essay that might be written from the opposite point of view, showing the injury done to our sugar industries by competitors armed with an artificial stimulus. I have dealt with that, and with the economic questions connected with it, in a little book entitled "A Short History of Sugar, 1856-1916, a Warning," to which I desire to refer my present audience. But as I made a passing reference to the injury done to our refining industry, as illustrated by the serious reduction in the industry on the Clyde from 240,000 tons per annum in 1882-86 to 125,000 tons in 1897-1910, it is necessary to point out that the cause of this collapse was the enormous importation of foreign refined beetroot sugar, at prices with which the unstimulated producer could not compete. For many years nearly a million tons were imported every year, the sugar being landed at every little port around our coasts. The Brussels Convention came into force in 1903, and the Clyde industry, which can work as cheaply as any refining industry in the world, revived. In 1918, the last year before the war, the Clyde refiners melted 231,333 tons, nearly as much as at the height of their remarkable prosperity in 1877-1886.

A distinguished—shall I say economist?—has recently proclaimed that "the millions should not be deprived of cheap sugar even if it be dumped." To this most attractive exclamation there are three most conclusive contradictions, founded on facts derived from the history of sugar during the last forty years. Those facts prove—first, that the fleeting pleasure of buying a commodity below cost price is disastrous to the consumer, because it is bound to be followed by reduced production and higher prices. Secondly, that under such circumstances the stimulated industry again takes the lead, increases its production, forces down prices once more, and gets one step further on the road to monopoly. That is exactly what happened with sugar. Thirdly, it is a fact that the millions have never been deprived of cheap sugar, except when there happened to be a bad beetroot crop, which is a periodical occurrence. Then prices go up. The dumped sugar, in which the consumer revelled, has made him more and more dependent on the beetroot crop for his supply; when that fails he has to pay the penalty. Then the war broke out, away went the whole of his dumped supply—and now, he is on rations.

These are the conclusive answers to this profound economist. He should begin by trying to master the rudiments of his subject.

[In the absence of Mr. George Martineau, C.B., the paper was read by Mr. Edward R. Davson, President of the Associated West Indian Chambers of Commerce.]

DISCUSSION.

The Chairman (The Right Hon. Lord Balfour of Burleigh, K.T., G.C.M.G., G.C.V.O.) thought all those present must have been greatly gratified by the paper which they had just heard, and would regret that Mr. Martineau was not present to appreciate personally the welcome which his paper had received. There were echoes in the paper of former controversies: it was not necessary to go back so far as the time of the Crusaders to find serious conflicts taking place over some of the points mentioned by the author. The reference to naval engagements and the sinking of sugar cargoes in the past was significant in view of what was taking place in that way at the present time. He had received a certain amount of elementary education in the subject of sugar from having been Chairman of the Commission that went to the West Indies some nine or ten years ago to arrange the preference between Canada and our West Indian Colonies, which he was glad to say had been successful, and was in operation at the present time. He had had a further education in the matter by having been Chairman of the Committee of Commercial and Industrial Policy after the War, whose report had been mentioned in the press during the last few days. He desired to urge that, in spite of the different views held on the subject, every one should as far as possible avoid the fiscal controversies which raged some eight or ten years ago. Consideration should be given to the question of whether any particular article was essential to our national well-being, and important, not only as a raw material for industries, but as an article for consumption by the population of this country. Attention should be given, in the second place, to the natural source of its supply; and, thirdly, to the risk of the supply being disturbed. The safety and security of our Empire and its population should be put first, and abstract principles should, to a large extent, take a back seat. In abstract principle he had always been a member of the Free Trade school, but he held that abstract principles, while they were extremely good servants, were very bad masters. Therefore practical and not theoretical conditions should rule the policy of this country. It was perfectly true that the capitalist must have some

security for the investment of his money if he was to produce articles for general consumption, and the paper showed how successful the German policy with regard to sugar had been. Due attention should be paid to the statement made by the Manchester Chambers of Commerce that "industries receiving such a stimulus are bound to become apathetic and inefficient"; but he thought it was going too far to argue that, because there was a risk that industries receiving preference might become apathetic and inefficient, no preference should ever be given. That amount of security ought to be given to the capitalist which would justify him in investing his money, but would not go so far as to give him a premium upon idleness and apathy and inefficiency. So far as sugar was concerned, at the commencement of the war and during the ten years previous to that date, this country derived a very large proportion of its sugar supply from enemy countries, and the point to be considered to-day was what this country could get from its own Imperial resources without taking a course which, on the one hand, would unduly raise prices, and, on the other hand, would set a premium upon idleness and apathy. The places within the Empire in which the cultivation of sugar was possible must be discovered, and attention must also be given to the question of the cost of carrying on that cultivation efficiently, and to the subject of the freights which had to be paid to bring the article to this country. Freights were in a state of great disturbance at the present time, and it was to be hoped that after the war they would be reduced to a large extent to their pre-war condition. This country must develop its own Imperial resources because, while he most earnestly hoped we should never be at variance either with the United States or with Holland, it was possible that the Ally or the Neutral of to-day might have different interests from ours in the future. If the resources of the Empire were to be developed a certain reasonable continuing security must be given for a period long enough to encourage the investor to put his money into the industry. He did not think it was impossible for this country to do with cane sugar what the Germans did with beetroot sugar, because in all probability the one was as susceptible of improvement on the right lines as the other. This country must pay greater attention to the interests and possibilities of its fellow-subjects in the Empire than it had ever done in the past. If that was done with a real desire to obtain a successful result he thought there was every prospect of success being achieved.

Sir Edward Rosling said he had listened to the paper with very great interest. Personally he was interested in the sugar industry in the very small and much-neglected colony of Mauritius. As a result of bounty-fed sugar, Mauritius for years was on the borders of bankruptcy, and it was only after the Convention that it was able to make a living at all. If after the war the market was again swamped with foreign and bounty-fed sugar, Mauritius would go back to the position it occupied in the past. He did not think protection would make the planters more or less inefficient, because the competition was too great, and even with protection they would have to do their best in order to make a living at all. It was only by organisation and help from the governing powers that the sugar industry of the Empire could be put on a thoroughly satisfactory footing.

Mr. C. Sandbach Parker, C.B.E., agreed with the Chairman that at the present time the people of this country must not allow themselves to be overruled by any fiscal views they might previously have held. They must consider the position as they found it to-day, and as they knew it would exist after the war. The Empire had to decide whether it was going to grow its own sugar or continue to buy it from foreign countries. He did not think any advantage would be gained by this Empire transferring its dependence from enemy countries to other foreign countries. The description given in the paper showed the wonderful results that had been obtained by America in her determination to provide herself with her own sugar supply. Some twenty-seven years ago America tried a system of free importation of sugar for about three years, but they very soon saw the mistake they were making. They realised that they were paying an enormous amount to Germany and to other countries in wages which they could perfectly well pay to their own people, and that they were at the mercy of those foreign countries for their sugar supply. They then reversed their policy, and set to work to build up their own industry by giving the preference to Cuba to which the Chairman had alluded, and by encouraging production in their own territory by giving freedom from Customs duties. The magnificent result obtained by that policy was the most conclusive answer to those theorists who said that preference promoted inefficiency. Except in those parts of the Empire which had a market at their own doors, such as Australia, South Africa, and possibly India, the sugar industry of the Empire had been deliberately stifled by the policy of this country, pursued now for about fifty years, in the belief that it benefited her people to have the cheapest supply of sugar, regardless of whether it was foreign or British grown. If, in 1870, the Government had offered the same inducements to the sugar-growers in the British Empire to improve their industry that were offered in Germany, this country would have been in a very much better position in that respect at the present time. It was commonly believed that during the war the sugar-growing colonies had made enormous profits. It was perfectly true that the price of sugar had been very high, but it was also true that everybody interested in the sugar industry had had to contribute to the cost of the war by means of the excess profits tax. During the war foreign countries, especially Cuba, had been able to gain

the whole of the enormous price to which sugar had been driven by the fact that this country had been dependent on enemy countries for its sugar supply, and during the war had been obliged to buy from other countries which were not supplying it before the war. Cuba had utilised its advantage to set its industry in the most magnificent order, and there was hardly an out-of-date factory in Cuba to-day. After the war this country would have to raise at least £700,000,000 a year of revenue as against £200,000,000 before the war, and all the industries of the country would be handicapped in two ways—(1) by having that millstone round their necks and (2) by having to compete against industries in those countries which during the war had been reaping the full benefit of war prices without having had to pay any part of the cost of the war. It was absolutely essential that any preference now given to the sugar industry should be adequate to produce the results that were required. The Empire was short of 2,000,000 tons at the present time, and if that supply was to be provided within the Empire within a reasonable time, adequate inducements must be given to the capitalist and to labour. It was no use starting with a very small preference, which might possibly promote inefficiency. It was very important to the sugar-using industries of this country to have a supply under British control. Before the war they had been relying on artificially stimulated supplies from Germany and other countries, and were now afraid that in future they would have to pay a great deal more for their sugar. He therefore wished to point out that an adequate preference would bring about an increase in the production of sugar in the British Empire, and, by increasing the world's supply, would reduce the cost of sugar to the sugar-using industries of this country. It would also give them a stable supply, well distributed over the Empire, and not liable to the tremendous fluctuations which resulted from being dependent on one particular part of the world. He was sure it would give the greatest possible pleasure to Mr. Martineau, if, as the result of the report of the Committee on Commercial and Industrial Policy after the war, the Government could be induced to adopt the views expressed in that report, and also the views expressed by the Chairman on the present occasion.

Mr. John R. Drake agreed with the author that the policy of the Government in connection with sugar had been absolutely murderous with regard to the sugar-producing efficiency of the Empire. At one time, taking the ordinary price of sugar as being roughly £10 a ton, the Continent was giving between £3 and £4 a ton bounty—that was to say, 30 or 40 per cent.—with the result that the price of sugar coming into this country from the Continent was reduced to £6 a ton. Our colonies naturally could not compete against that. Having been in business in Germany for many years, he believed that the German policy had been adopted by the German producer and the German Government with the deliberate intention of murdering the British industry in sugar, and also as much as possible the sugar industries of other competing countries. Like the Chairman, he was theoretically a Free Trader. By Free Trade he meant that each country should have the right and power to develop itself on its natural lines; but our colonies had been prevented from developing themselves in that way by the deliberate attacks of the German nation and the German sugar industry. Scientists and capitalists could not be expected to do their best against a Government attack such as he had described. A reasonable amount of help given to our industries would not make them apathetic and inefficient; it was the hopeless position they were in which had in some cases perhaps made them rather inefficient. He agreed with the Chairman that the amount of protection given should be such that it would not improperly raise the price of sugar to the working-classes of this country and should not be such as to create inefficiency and idleness. He believed that the protection afforded should be reasonably limited, and he thought that was also the Chairman's view. He did not agree with Mr. Sandbach Parker that it was possible for this country to obtain all its sugar supply from within the Empire, and surely it was impossible to imagine such a fiscal system being introduced as would prevent there being a certain amount of interchange of articles between ourselves and other countries, and one of the things that, within reasonable limits, we might expect to import would be sugar. Taking into consideration the fact that the sugar industry of the British Empire was to a large extent an infant industry, and therefore deserving of help, he quite agreed that such help should be given to it by the Government as would enable it to fight the preferences given by other countries.

Mr. P. C. Lyon thought the paper preached a moral which was not altogether political, and that the author had shown that, to a very great extent in the history of the sugar industry, science had come into its own. The state of scientific research in this country was not of the happiest description even now, although a great improvement had taken place during the last few years. Private firms engaged in the sugar industry had worked very hard to carry out research, but it still remained a fact that a great deal of research, both in the sugar and other industries, was done by overworked professors at universities. When the Germans took the matter up they paid their men adequately, and they engaged a number of scientists to deal with the question of beetroot sugar, with the result that very large firms were established, providing so great an amount of beetroot sugar that the very difficult scientific problems of making every possible use of the by-products of sugar could be dealt with. Germany went even further than the United States or France—first, in the extraction of the sugar from the pure juice of the

beetroot, then in the further extraction of sugar from the molasses, and finally in the production of valuable chemical products from the residue that was left after every single particle of sugar had been extracted. There was a great deal to be done in fundamental research which could not be undertaken by private firms, but could only be carried out by the industry by means of co-operation on a large scale. It was an encouraging matter that a move had been made by the Empire Producers' Organisation and by a committee appointed by that organisation for the establishment of co-operation in research on a large scale. A good deal had been done in the West Indies and in India by scattered investigators on the agricultural side of growing the cane, but Agricultural Departments were starved all over the world, and the stimulus which the industry could give the Government was required to get better and further work done. If politicians took the matter up, they would be in a far better position to meet the arguments of those who opposed them if they were perfectly certain that the firms engaged in the industry were doing all they could, individually and collectively, from the scientific point of view.

Monsieur L. Soucher said that the paper dealt chiefly with the sugar cane, but he thought there were immense possibilities of sugar production in England, which certainly should enable this country to avoid importing sugar at least from enemy countries. It was extraordinary that the efforts which had been made in England to increase the food production always lost sight of the fact that one of the most important factors to increase the yield of wheat and corn was the cultivation of beetroot. On the Continent, in a good many instances, no profits had been made on the actual cultivation of the beet itself, but it was being cultivated because it brought enormous advantages to the following crops. He believed that in England a very large quantity of sugar could be produced from the cultivation of the beetroot to supplement the sugar which the Colonies produced, and that this country could thus be enabled entirely to avoid enemy producers.

Mr. R. Rutherford (Chairman, West Indian Committee) was glad to find that, although the Chairman and Mr. Drake both expressed the view that they were Free Traders, they qualified their Free Trade. He had always thought that the essence of Free Trade was the survival of the fittest, but that had certainly not been the case with regard to sugar. In his opinion cane sugar was the fittest, but it had not had that opportunity of surviving. He thought Mr. Drake, in saying that he did not believe this country could obtain all the sugar it required from within the Empire, forgot that that was entirely due to the fact that the cane-sugar industry of the Empire had been strangled.

Sir Herbert Matthews said he was chiefly interested in the sugar-beet industry in this country, and believed that there ought to be a great future for that industry. The cultivation of the beetroot would not be displacing other articles of food, but would in its by-products furnish a very valuable and badly-needed cattle food, and would improve and increase the following crops. There were, however, one or two passages in the paper which made him hesitate at the moment to encourage a very large outlay on the introduction of that industry, because the author pointed out the probability of a very large increase in the cane-sugar industry of our Colonies and Dominions. If that increase took place, unless some assistance of a fiscal character could be obtained from the Government, he felt rather nervous as to the future of the sugar-beet industry in this country, which was an infant industry, and would have to go through all the struggles of a new industry. Assistance was needed from the Government for a sufficiently long period to encourage investors to put capital into the industry, which he was confident would be a paying concern to the capitalist and of the greatest help to food production in this country.

Mr. William Martineau said the author emphasised the importance of research as applied to sugar, and personally he was taking part in that research. The British Empire Producers' Organisation had founded an Empire Sugar Research Association, of which he was the honorary secretary. The Association had the support of every sugar-producing colony in the Empire, and of practically every sugar-using industry in England, and was working in close touch with the Government Research Committee. He hoped the efforts of the Association would be of some assistance in reinstating the sugar industry in the British Empire.

Mr. S. Barnett wished to point out that in a period of fourteen years the production of sugar in the United States, in the colonies of the United States, and in Cuba, to which a preference was given, increased by no less than 3½ million tons, the increase in Cuba alone being practically 2½ million tons. If the United States had not adopted the policy of preference twenty years ago, this country would now have practically no sugar at all, and he thought the British Government ought to adopt a similar policy, and should think rather more of the producer and less of the consumer. If a substantial world-wide increase took place in the production of sugar, however, the probability was that the consumer would not have to pay more.

Mr. C. Sandbach Parker said that, with regard to the possibility of the Empire producing within a reasonable time all its requirements in the matter of sugar, to do that the stimulus must be

adequate. Mr. Drake had stated that he believed in every country producing what it was naturally best fitted to produce, and Mr. Rutherford was quite right when he said that the British countries best fitted for the production of sugar had been strangled and driven out of the market. Mr. Drake had urged that any preference given should be small, in the interests of consumers. He, on the contrary, felt that the consumers' interest would be best served by securing a cheap and well-distributed supply, which would be most quickly attained by giving adequate security for the rapid development of the industry within the British Empire.

Mr. Edward R. Davson said he was very glad to have had the pleasure of reading the paper with Lord Balfour in the chair, and desired to pay a tribute to him for all that he had done for the sugar industry.

On the proposition of the Chairman, a hearty vote of thanks was passed to Mr. Martineau for his interesting paper, and to Mr. Davson for reading the paper, and the meeting terminated.

PRODUCTION OF PERILLA OIL AND OIL PAWLOWNIA IN JAPAN.

Dealers in Yokohama estimate that the average annual crop of perilla seed in Japan is approximately 1,000,000 kin (1,330,000 lb.). According to statistics of the Japanese Department of Commerce and Agriculture, 1,283,662 United States gallons of perilla oil, worth £144,000, and 930,436 gallons, valued at £101,000, were produced in Japan in 1912 and 1913 respectively, the latest years for which statistics have been compiled.

An oil used in Japan in the manufacture of oil-paper and paints, and for illuminating purposes, is obtained from the fruit of a tree known under various names in Japan, but scientifically called "abura-giri" ("oil pawlownia") by Japanese, and *Aleuritis cordata* by European botanists. This tree grows wild in Japan, and only five years ago it was for the first time, on a very small scale, cultivated for commercial purposes.

The regions where most of these trees are to be found are on the coast of the Japan Sea, on the main island of Japan. Trees growing on slopes facing the sea and exposed to sea winds produce the best nuts, or those containing the most oil. One that grows wild requires ten years before it bears its first crop of nuts. By fertilising, a tree may be made to bear fruit four years after it is planted.

The use of the "oil pawlownia" product has been known in Japan for a long time, but, according to a report by the United States Vice-Consul at Yokohama, has not yet acquired any commercial importance. The oil is extracted by the most primitive methods (drying, pounding, steaming, and crushing) by producers on their farms. Japan's output is about 1,500,000 bushels of nuts annually, from which 238,300 gallons of oil are obtained. None of this oil is exported from Japan. Shells and kernels crushed together give 36·1 per cent. of oil, while 48·85 per cent. of oil is obtained from the kernel.

TUNNY FISHERIES IN KYUSHU.

Tunny are caught along the Pacific coast of Japan, from Formosa as far north as the Hokkaido. The total annual catch varies greatly, but the average for recent years has been 25,000,000 pounds, valued at £200,000.

In Kyushu the most profitable tunny fisheries are found along the south-eastern coast of the island. Large trap-nets, 150 to 300 feet wide at the mouth and 500 to 900 feet long, are favoured in this district. The rope for the nets is about ¼-inch in diameter and is made of rice straw. While not as strong as hemp rope, it is more clearly visible under water and serves better to keep the fish within the desired limits. The mesh of a trap-net at the mouth is very large (about 3 feet), but decreases in size, with the distance from the mouth, down to as small as 1 inch. The net is set in 35 to 40 fathoms of water, with the mouth facing the direction from which the fish are running. A net of straw rope, with a 3-foot mesh, is stretched from the trap-net to the shore, and another net of the same sort is stretched from the trap-net well out across the course usually followed by the fish.

Two large boats, each about 40 feet long, and three to five smaller boats are used in placing the nets. When large schools are running an additional boat remains after the nets are placed, with an extra net to be used as needed to guide the fish into the desired course. Men stationed on heights overlooking the sea watch the course of the schools of fish, and signal to the men in the boats the proper direction in which to extend the nets.

According to a report by the United States Vice-Consul at Nagasaki, bays surrounded by high, well-wooded hills are considered the best places to catch tunny. The fish move from south to north in the spring, and from north to south in the latter part of the year. Tunny, as they enter a bay, circle around and leave it, following a fairly definite course, which is well known to observers. The local fishermen are guided by this knowledge and by a general familiarity with the annual migrations in selecting the places for the nets at the several seasons of the year.

The nets are usually drawn two or three times a day—at dawn, in the afternoon, and at midnight. When the fish are running in large schools and frequently, the nets are drawn as often as necessary to keep them clear. As the straw rope is not very strong, it is occasionally necessary, with an unexpectedly large haul, to take in the catch with a hemp net dropped inside the net of straw rope.

Fishing for tunny requires considerable outlay

of capital. It is necessary to pay a stated amount annually to the Government for the fishing rights, and to have sufficient capital to repair or renew the nets as frequently as may be necessary, whether the catches are large or small. A trap-net costs from £40 to £50, according to size, and seldom lasts longer than one season. Sometimes a period of small catches continues for several years, to be followed by a year or two of extraordinarily large catches. The years of plenty must yield profits large enough to make good the scarcity of the preceding years. Capital sufficient to maintain the business through years of loss is indispensable for ultimate success.

In the last few years Kyushu, as compared with other parts of Japan, has not gained much from its tunny fisheries. Under present conditions, a haul of ten to fifteen average-size tunny is not considered poor luck. This decline is not expected to last, and the fishermen confidently look forward to a return of the years of plenty.

Tunny is nearly always consumed in the local markets. It is very highly esteemed when prepared in the form of "sashimi" (the raw meat thinly sliced and served with soy sauce). Small quantities are canned, or dried after being boiled, and in that form it is sold as "katsuobushi" ("dried bonito," the bonito being usually preserved in this form).

The Government does not give direct financial aid to the tunny fisheries. It makes every effort, however, to preserve conditions favourable to the fishing industry. Care is taken to prevent deforestation of the hills surrounding bays which the fish frequent. There are several Government experiment stations where the forms and sizes of nets adapted to each variety of fish are studied, and where investigations of the seasonal habits of fish are conducted.

THE SWISS TOY INDUSTRY.

Until recently the manufacture of toys in Switzerland had not attained much importance. There were a few small factories in operation (three devoted exclusively to the manufacture of toys and several where toys were made in connection with sporting goods, wood carvings, celluloid articles, etc.), but their products were sold mainly in the domestic market. The foreign trade in Swiss toys was not large, amounting to £8,400 in the pre-war year 1913, and dropping to half that sum in 1915.

However, the war has brought about a general readjustment of practically every branch of activity, the toy industry included. Shortly after the outbreak of hostilities, the question was raised as to how the production, and at the same time the variety, of toys could most advantageously be increased in Switzerland. The reason for this interest in toy-making was that thousands of men who were formerly employed as carvers had been thrown out of work when the war brought the wood-carving industry to a standstill. These men were without means, and were unable to make a living for their families in any other way. The attention of the Federal and Cantonal Governments was called to the great similarity between wood-carving and toy-making, with a view to obtaining their approval of a movement to combine the two industries. The wood-carving industry being chiefly centred in the Bernese Oberland, the people in that district united to support the plan.

It was not the intention of those at the head of the movement to found new factories or encourage the investment of capital for the enlargement of plants already in existence. Their plan was to provide work for those men who, owing to the war, were thrown out of their regular employment; and the only way to do this under the circumstances was to organise a new home industry similar to what the wood-carving industry used to be. The natural result was that preference was given to making toys, and especially wooden toys. The matter was taken up in a most energetic manner, and no efforts spared to establish the new industry at least temporarily.

It appears from a report by the United States Consul-General at Zurich, that it has not been an easy task to introduce an almost new industry during war time. Not only are raw materials much higher in price, but they are also harder to obtain than under normal circumstances. Wages also have increased, and high freight rates, war insurance, etc., have adversely affected the industry. But in spite of these drawbacks the people in the Bernese Oberland were successful in obtaining Federal and Cantonal subsidies with which to purchase the necessary machines, tools, and models, and the manufacture of toys is now being taken up with great activity. Special courses are being given, in which the mechanical part of the industry is taught and workmen are thoroughly trained.

In order to familiarise Swiss buyers with the home-made toys, exhibitions were held in various large cities of the Republic. A fairly large variety of toys was displayed, some of the exhibits giving evidence of exceptionally skilled workmanship. Optimistic observers see no reason why this industry should not be permanently maintained, regardless of what conditions after the war may be. It is hardly likely that the competition of Swiss products in foreign markets will be soon felt, for the demand for toys in Switzerland so far exceeds the domestic production, that it will be some time before foreign outlets are needed.

As stated, Switzerland's export trade in toys is not large, and is quite overshadowed by the imports. Germany, Austria-Hungary, France,

and the United Kingdom are the chief suppliers of these imported toys; and, notwithstanding its own immense production, Germany normally is the best buyer of Swiss playthings.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Taxable Clothes.—It seems a foregone conclusion that the luxury tax will apply to specified kinds of clothing, and no doubt a case in its favour can be easily made out. The objections, however, are not negligible, and it would be comforting to feel sure that the industrial reactions have all been carefully thought out. The French, in their haste, have classified silk stockings and underwear as articles which must, in all circumstances, bear tax upon their retail sale; yet it might be very difficult to show that real silks are intrinsically more luxurious than hosiery made of any other materials. A copy of this error should be easy to avoid, and presumably the British luxury taxes upon apparel and furnishings will fall upon goods selling at more than an allotted price. The number of bare textiles coming under tax should not be great, and it is permissible to suppose that the burden will be principally indirect and incurred upon the articles into which the finished products of textile industry are wrought. Even so, and allowing that money is prodigiously plentiful, the prospect is none too pleasing.

A Tariff on Art.—The production of idle luxuries may be a thing always to discourage, but to do this it is useless to make price the criterion. Cheap superfluities are more abundant than expensive ones. Garments at a high price are generally those into which enter the higher qualities of material, the finer efforts in design, and the most skilled workmanship. The ultimate price is not due nearly so much to the cost of the woven material as to the subsequent additions of dressmakers and distributors. If this price be driven down, the temptation to take the reduction out of the cost of material is strong; and if the effect be to run the price up, the time will come when the process restricts the sales of the finer products of textile industry. In either event an important humanising influence is lost, and in one measure or another it is sincerely to be feared that the attempt to tax luxuries will be prejudicial to the artistic development of industry. If it can be conceded that the profits will be one and the same, it is still not a good thing to discourage the production of the higher sorts of goods, and any mistake of that kind will have to be paid for in meal or in malt. The harm can be minimised by taking thought, but signs are all too few of anything more than a superficial examination.

Compensatory Markets.—It is not to be expected that spinners and others who found their sale or their chief market in Germany and Austria should share the full emotional fervour of the boycotting enthusiasts. Their tendency to exaggerate the importance to this country of the Central European markets may be set against the countervailing disposition to assume that these old outlets for yarn do not matter to our economy. The vital question is whether these Continental openings can be replaced, and upon this point Lord Balfour's Committee ventures an interesting opinion. It is believed that compensatory markets can be found for the wool tops, worsted, mohair, and alpaca yarns formerly sold to Germany, and that the fine cotton yarns lately consumed in that country can all be consumed in this and allied countries. Positiveness upon that point would be welcome, for there are various signs showing that access to English yarn supplies will by no means be despised by German consumers after the war. German textile operatives call, in a recent manifesto, not only for the free import of raw materials and yarns, but for fabrics and ready-made clothing. Their plight as consumers presses more heavily than their interest as producers. Herr Dettmann's public fears that the German market will be thrown open to all comers if raw materials are withheld from it are to the same point.

Cellulon.—Not often are so many inconsistent stories published about one and the same article as about the new German hope, cellulon. All accounts agree that it comes from wood-pulp, and that it is not made in the familiar way by twisting ribbons of paper into round thread. It is variously supposed to be exuded from small holes in a plate; to be moulded from wet pulp in passing over grooved drums; and to be a combination of waste cotton or wool-fibres and cellulose. It is commended as a thorough substitute for cotton, hemp, jute, and linen—which means presumably that a thick yarn can be made from it—and there is impartial, inexpert testimony that one sample of the cloth seemed very strong. Out of this welter of conflicting reports the safest supposition would seem to be that cellulon is a manufactured product, not of finished paper, but of paper-makers' half-stuff. It may be strong, and may be rendered more or less proof against water, but as nobody ventures to call it also light it may be believed to share the common heritage of these paper products. Factories to manufacture the stuff are going up, and in all probability good prices will be obtainable for it, in the absence of much better material. All the flattering accounts of the enemy's textile substitutes come from suppliers of the articles; the users employ resigned tones.

A New Journal.—In its guise as a monthly publication, the *Journal of the Textile Institute* is a vehicle for the proceedings of the parent body and for the communications of textile technologists. It sets, among textile periodicals, a new standard of concision of statement for which it may be hoped that a growing number of appreciators will

be found. The abstract of technical literature occupying one-third of its pages naturally does not rise any higher than its sources, and may be said to relate to documents of varying significance and value. The Journal will fulfil its predestined office in attracting to itself the original communications of discoveries made by specialists, and in this direction one example may be left to encourage another. In industries not far remote from the textile manufacturing trade there are admirably successful journals of the type that this one is endeavouring to become, and, given time and opportunity, the Institute Journal should establish itself impregnably also.

The Textile Institute.—The attention of testators and other custodians of wealth may be drawn pointedly to the £50,000 fund now being established under charge of the Textile Institute for the endowment of researches into the nature of textile fabrics and their uses in industry. Large sums of money have been somewhat easily made during the war by parties to the textile business, and the claims of its future should not need much pressing. Noble uses for money jostle each other in these days, but there need be no mistaking the nobility of aim implied in setting upon a scientific basis an industry which is the means of life to one and a quarter million people. So far as such a thing can be secured, the vesting of control in the hands of a body like the Textile Institute ensures competent administration, and the fund presents itself to those who have acquired wealth as a ready means of repaying an obligation.

OBITUARY.

The Earl of Rosse.—The Earl of Rosse, who had been a member of the Royal Society of Arts since 1909, died at his residence, Birr Castle, on the 10th inst., at the age of forty-four.

William Edward Parsons, fifth Earl of Rosse and eighth baronet, succeeded his father, who had also been a member of the Society for many years, in 1908. After being educated at Eton and Christ Church, Oxford, he entered the Coldstream Guards, whence he was transferred to the Irish Guards. He served in the South African War, and was awarded the Queen's Medal with three clasps. At the outbreak of the present war he rejoined the Irish Guards, and was severely wounded in the head in 1915. From this wound he never really recovered, and it was doubtless indirectly the cause of his sudden death.

GENERAL NOTES.

The Canal Question.—*Engineering* urges that in any great scheme of canalisation, such as is suggested as a post-war measure, we should find our capital expenditure out of all proportion to that of our Continental rivals, while the cost of maintenance and operation per mile and per ton would be excessive. Most of the Continental industrial districts, which are so well served in the matter of water transport, are comparatively flat, whereas in the United Kingdom the majority of similar localities are hilly. In Continental Europe there is only one lock for every five miles of inland navigation; here, taking the country through, there is a lock for every 1½ miles. Of our navigable inland waterways—4,053 miles—1,482 miles are natural river; in France, 4,392 miles out of 7,006 miles are natural; in Germany, 5,815 miles out of 7,038 miles; in Austria, 2,427 miles out of 2,722 miles; and in Russia, 23,211 miles out of 23,614 miles. When a year ago the Government took over the inland waterways it guaranteed the canal companies, but not the carriers, their net revenue of 1913. The carriers, by whom 90 per cent. of the traffic is done, are companies and individuals who own the barges and pay the canal companies for the use of the waterways. The *Times* states that the Canal Control Committee, of which Sir Maurice Fitzmaurice, C.M.G., is the chairman, has made financial recommendations to the Board of Trade for the purpose of enabling the carriers to fix rates that will divert additional traffic to the canals and pay the high wages which labour now demands. At the time the Government assumed control 1,200 barges were lying idle for want of crews. Large numbers of bargemen had joined the Army, and most of those who were ineligible as recruits were attracted to the railways and munition factories by higher wages. It is claimed that, despite adverse circumstances, the Canal Control Committee has already done much to relieve the congestion of the railways.

Concrete Ships.—Replying to questions in the House of Commons recently, the Civil Lord of the Admiralty said that the first concrete vessels were built in Italy, but they were of small dimensions and of no commercial value; in fact, some of them were rowing boats. One concrete vessel, with a dead-weight carrying capacity of 5,000 tons, had been launched in the United States, but it was not likely that it would come to this country. Every encouragement was being given by the Admiralty to this new industry, several newly-formed yards having been laid down specially for constructing concrete craft, while existing shipyards had been encouraged to form branch establishments for the same purpose, without interference with the building of steel vessels. Although at present no vessels of more than 1,000 tons were being constructed to the order of the Admiralty, there was a very urgent demand for vessels of small tonnage which could be rapidly constructed. In view of this, it was decided to concentrate on the smaller craft until more experience had been obtained as to the construction of such craft, and what was of much more importance, behaviour when at sea.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Sixty-fourth Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new Fellows, will be held, in accordance with the By-Laws, on Wednesday, June 26th, at 4 p.m.

(By order of the Council),
GEORGE KENNETH MENZIES, *Secretary.*

INDIAN SECTION.

Thursday afternoon, June 20th; The RIGHT HON. E. S. MONTAGU, M.P., Secretary of State for India, in the chair. A paper by the HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, on "Indian Cotton and the Cotton-Mill Industry," was read by SIR CHARLES H. ARMSTRONG, late Chairman, Bombay Chamber of Commerce.

The paper and discussion will be published in a subsequent number of the *Journal.*

EXAMINATIONS.

The results of the Stage I. (Elementary) Examinations, which were held from March 18th to 26th last, were sent to the centres concerned on the 18th inst. The results of all three stages of the March examinations have now been made known.

The time-tables of the 1919 Examinations have also been issued. The Easter examinations will be held from Monday, April 7th, to Monday, April 14th.

Those held at Whitsuntide will begin on Monday, May 26th, and finish on Wednesday, June 4th.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 24 ... Geographical Society, Burlington-gardens, W., 8 p.m. Address by one of the Canadian Ministers attending the Imperial Conference.

TUESDAY, JUNE 25...Royal Dublin Society, Leinster House, Dublin, 4.15 p.m. 1. Dr. F. E. Hackett, "The Twist and Magnetisation of a Steel Tube in a Spiral Magnetic Field." 2. Mr. R. G. Allen, "The Absorption of Water by Vulcanised Fibre and Erinoid on Exposure to Moist Air, and the consequent Change of Electrical Resistance." 3. Dr. F. E. Hackett, "A Method of Obtaining Dry Steam without a Steam Trap."
Aëronautical Society, Central Hall, Westminster, S.W., 7.30 p.m. ("Wilbur Wright" Lecture.) Dr. W. F. Durand, "Some Outstanding Problems in Aëronautics."
Anthropological Institute, 50, Great Russell-street, W.C., 5 p.m. Mr. S. Ishii, "Sociology of the East Coast People of Formosa."

WEDNESDAY, JUNE 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Annual General Meeting.
Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. A. M. Williamson, "The Housing Problem."

THURSDAY, JUNE 27...Royal National Pension Fund for Nurses, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Annual Meeting.
British Acetylene and Welding Association, Holborn Restaurant, W.C., 2.30 p.m. Mr. C. Bingham, "The Purification of Acetylene."

FRIDAY, JUNE 28...Chadwick Public Lecture, at the Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Professor D. W. Thompson, "Our Fisheries and the Food Supply. Lecture II.—The Catch by Net—or the Great Herring Fishery."
Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Professor E. H. Barton and Miss H. M. Browning, "A Demonstration of Coupled Vibrations." 2. Mr. I. Williams, "A New Method of Measuring Alternating Currents and Electric Oscillations."

SUPPLEMENT to the Journal of the Royal Society of Arts, June 21st, 1918.

ROYAL SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE

165th SESSION, 1918-1919

BALLOTING LIST, WEDNESDAY, JUNE 26th, 1918, 4 p.m.

President.

H.R.H. The Duke of Connaught and Strathearn, K.G.

Vice-Presidents.

(Twenty-two to be elected.)

Sir Steuart Colvin Bayley, G.C.S.I., C.I.E. ....
Lord Blyth ....
Sir William Henry Davison, K.B.E., D.L. ....
Sir (Frederick) William Duke, G.C.I.E., K.C.S.I. ....
Sir Walter Egerton, K.C.M.G., LL.D. ....
Peter MacIntyre Evans, M.A. ....
Sir Robert Abbott Hadfield, D.Sc., D.Met., F.R.S. ....
Field-Marshal Sir Douglas Haig, K.T., G.C.B., G.C.V.O., K.C.I.E.
Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc. ....
Lord Islington, P.C., G.C.M.G., D.S.O. ....
Lord Leverhulme ....
Major Percy A. MacMahon, R.A., LL.D., Sc.D., F.R.S. ....
Sir Philip Magnus, Bt., M.P. ....
Viscount Northcliffe ....
Major-General Sir Desmond D. T. O'Callaghan, R.A., K.C.V.O.
Major Francis Grant Ogilvie, C.B., LL.D. ....
Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.
Hon. Richard Clere Parsons, M.A. ....
Sir Boverton Redwood, Bt., D.Sc., F.R.S.E. ....
Lord Sanderson, G.C.B., K.C.M.G. ....
Alan A. Campbell Swinton, F.R.S. ....
Sir Aston Webb, K.C.V.O., C.B., R.A. ....

Ordinary Members of Council.

(Twelve to be elected.)

Sir Charles Carrick Allom ....
Sir Dugald Clerk, K.B.E., D.Sc., F.R.S. ....
Edward Dent, M.A. ....
Martin Onslow Forster, D.Sc., F.R.S. ....
Major Edward Humphrey Manisty Leggett, R.E., D.S.O. ....
William Henry Maw, LL.D., M.Inst.C.E. ....
Sir Francis Taylor Piggott, M.A., LL.M. ....
John Slater, F.R.I.B.A. ....
James Swinburne, F.R.S. ....
Professor John Millar Thomson, LL.D., F.R.S. ....
John Augustus Voelcker, M.A., Ph.D., F.I.C. ....
Sir Frank Warner, K.B.E. ....

Treasurers.

(Two to be elected.)

Carmichael Thomas ....
Sir Henry Trueman Wood, M.A. ....

Secretary.

George Kenneth Menzies, M.A.

Bye-Law 69.—"Every member *whose subscription is not in arrear* is entitled— . . . To be present and to vote at the Annual and all other General Meetings of the Society."
Bye-Law 83.—"Every member intending to vote at the election of officers may, if he shall think fit, erase any name or names from such Balloting List, and may substitute in the place thereof the name or names of any other qualified person or persons, and shall hand in to the Chairman such Balloting List as aforesaid, either with or without such erasure and substitution of names."
"Any Balloting List containing a greater number of names proposed for any office than the number to be elected for such office shall be absolutely and wholly void, and shall be rejected by the Scrutineers."

N.B.—The names in Italics are those of Fellows who have not filled the offices for which they are respectively proposed during the current year.

NO BALLOTING LIST can be received unless presented by the Fellow IN PERSON at the Meeting.

PROCEEDINGS OF THE SOCIETY.

TWENTIETH ORDINARY MEETING.

Wednesday, May 8th, 1918; SIR EDWARD ROSLING, Chairman of Council, Rubber-Growers' Association, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barouch, Ladislas, London.
Brown, George, Greenock.
Clapperton, George, Oxford.
Claus, William Henry, Alderley Edge.
Fryer, Frederick George, M.I.Mech.E., York.
Pugh, Ralph John, London.
Talbot, Benjamin, Middlesbrough.
Taylor, Alderman Herbert, J.P., Eaglescliffe, Co. Durham.

The following candidates were balloted for and duly elected Fellows of the Society:—

Brown, Joseph Pearce, J.P., Plymouth.
Kingsford, William Edward, Cairo, Egypt.
McConnel, John Wanklyn, M.A., Manchester.
Ramsay, Alexander, Lincoln.

The paper read was—

SCIENCE AND THE RUBBER INDUSTRY.

By J. BRETLAND FARMER, M.A., D.Sc., F.R.S.,
Professor of Botany, Imperial College of Science and Technology.

I have been asked to give an address on the use of science to the rubber industry. The subject is much too large to be fully discussed in the time at our disposal this afternoon, and I am not going to attempt to deal with other than certain aspects of the matter with which I may claim to have some familiarity. But, after all, these happen to be among the more important aspects.

I propose, then, to invite your attention to a consideration of the nature of the services science has rendered to the plantation industry in the matter of the production of the raw rubber, and, without going into too great detail, to indicate the directions in which it appears that the industry can profitably make further use of such assistance.

As soon as we regard the matter carefully it becomes apparent that we are still lacking in a true perception of the relations that should exist between science on the one hand and such an industry as that of rubber-planting and producing on the other. Agriculture, generally, is at bottom an essentially scientific industry. Its carrying on, and especially its reasonable extension, depends fundamentally upon the utilisation of natural knowledge, which is natural science. The knowledge may be largely empirical, it may be very imperfect, but it must be there in some measure; indeed, below a certain level of knowledge the tracks are apt to lead straightway towards insolvency. In tropical agriculture this truth is more evident than at home. But that is only because in Europe we have a wide experience, reaching back for many generations, to go upon. In the tropical cultivation of the ancient crops practice is also, up to a point, admirable if somewhat stereotyped, just

as it is among the old-fashioned folk at home. But a *new* industry, developed under modern financial and other conditions, calls for new practice. New wine is said to burst old bottles, and we have had already some sharp lessons in the tropics on the folly of neglecting to get Nature ranged on our side in exploiting the natural wealth which lies to the hand of him who knows how to gather it.

Such an industry as that of plantation rubber is essentially a branch of applied science. The trouble that lies at the root of things is that people do not sufficiently realise what they mean by science at all.

Let me put the matter in another way. We can of ourselves never produce anything in this world—neither rubber nor anything else of a material kind. We cannot make a rubber-tree, nor can we make it grow or yield anything. What we can, and actually do, effect is to arrange the conditions within certain rather narrow limits, but the rest of the affair—the genuine constructive work—lies altogether outside our powers. It is here that knowledge comes in, the knowing of the conditions which are requisite in order that what we desire may be accomplished by the forces of Nature, so far as it may be within our power to co-ordinate their operation, and so to secure the object we have in view. This is why it is so much easier to destroy than to construct. A relatively small derangement is enough to bring about destruction; sustained effort and continual watchfulness are demanded to ensure that the forces we imperfectly understand, and only partially control, may act in the desired way over a period of time which may be, and commonly is, of long duration.

I have tried to make this fundamentally important matter as clear as I could in order to emphasise the real relations in which what we call science ought to stand towards the planting industry—or for that matter towards any other business which is concerned with the material and forces of Nature—if the industries are to get out of science anything like all the advantages she has to offer.

How, then, does the particular sort of knowledge which we call science differ from that which is reached by the empirical method of trial and error? As we have seen, the latter can carry us very far, though it is expensive to acquire. In ordinary agriculture it has taken us a long way and has reaped a large measure of success. But it has been acquired wastefully, and many of the trials have been ruinously unprofitable. Now it is the chief business of science to detect the hidden relationships of cause and effect. The phrase may be simple but if you try to analyse it, and to see what it really implies, you will soon discover it is not so simple as it looks at first sight. In Nature we hardly ever encounter a straightforward problem. Before it can be usefully attacked it has to be split up into a number of more elementary ones—easier to grapple with, but, unfortunately, not always easy to solve. When we have disentangled, or analysed, the immediate problem into its simpler components, and some of these have been more or less fully unravelled, we have really learnt much which, though perhaps not directly convertible into cash value, may well put us in a position so to improve empirical practice that the cash will flow in.

The German chemists spent large sums of money, variously estimated at a million or more sterling, in breaking up the big indigo problem into its simpler parts before they had found out enough about the matter to enable them well-nigh to ruin the indigo plantations with their synthetic product. Similarly, unless we succeed in properly and intelligently harnessing the natural forces, and in manipulating the natural material basis for the plantation rubber, it may well happen that the chemist will discover how to bring about, on a commercially paying scale in the factory, what the rubber plant effects within its own body—the production of caoutchouc. If he ever does this on a successfully competitive scale, the planting industry will have itself to thank for the closing down of the plantations. The raw materials, chiefly carbon dioxide and water, are available everywhere, and are abundantly at the disposal of the plant, while the sunlight which drives the living machinery is free to utilise. And if the planting industry fails to keep uppermost in a competition where the rival is handicapped with relatively costly raw materials, it will be due to a short-sighted reliance on defective or depreciated plant, and possibly to unimproved vital machinery which is not being economically driven by the sun's energy. In other words, to a neglect of disease and to a lack of breeding better strains of rubber plants.

It is fair to learn from others, even from our enemies. Thirty years ago the yield of sugar from sugar-beet was scarcely half what it is to-day. The agriculturists, largely German, co-operating with scientific men, rapidly improved their strains of beet, and succeeded in

largely undercutting the product of the sugar-cane, mainly because the West Indian planters continued to employ methods—if they could be called methods at all—which could hardly end in any way but disaster. I well remember the surprise I felt some thirty-five years ago at finding a beautifully equipped laboratory attached to a very small factory erected for the extraction of sugar in a Hartz mountain village. The laboratory was provided with all the latest apparatus, and was in the charge of a very able man. Nothing was left to chance, and every effort was made to understand the how and the wherefore of sugar production, not only from the beet in the factory, but from the raw materials in air and soil when they meet within the tissues of the beet. In such centres, and they were many, knowledge was being made, and although the problems that confronted those early inquirers were far less susceptible to analysis at that time than at the present day, the patient and dogged determination to improve the stock and the methods has justly earned a rich reward.

Now let us turn to the rubber industry and try to see how we stand in this matter. After a number of tentative attempts with a variety of rubber-yielding plants—*Ficus, Castilloa, Funtumia, Manihot* (Ceara), and others—the plantation industry has mainly centred its efforts on *Hevea*. It is not necessary to detail here the romantic episode of its acquirement, through Wickham, by Kew, and its distribution by that great establishment to the tropical regions of the Empire. But it should not be forgotten that this great wealth-producing agency in the British Empire was cradled in the scientific nursery at Kew. As it advanced to the productive stages it has continually invoked the assistance of science, which has been repeatedly able to short-circuit the dangerous and devious road of empiricism—a road strewn with the corpses of more than one industry, as in Ceylon and elsewhere. Soon after its introduction the inevitable onslaught of disease occurred. At first came the serious attack of *Fomes*, and mycologists were engaged to study the fungus and to devise remedial measures. That particular disease is now pretty well understood and under control, and I have met men who are inclined to think that the value of the scientific assistance rendered in that connection has been somewhat overrated. Such an attitude is plainly untenable. Because the remedy happens to be simple when you know what to do, when to do it, and how to apply it, the value to the industry of being in a position to adopt remedies at all is supreme. Such measures, however, could have only been employed when the full story of the cause of the disease had been elucidated, and for this the scientific methods of men specially trained in the laboratory and in the field were absolutely indispensable. When *Fomes* had been pretty well subjugated it was supposed by some that the troubles were at an end. But those who were accustomed to think in terms of cause and effect, whether they called themselves scientific or practical men, knew better. You cannot grow a huge, and practically continuous, acreage of any species, especially under tropical conditions, without a constantly present risk of the incursion and rapid spread of animal or vegetable pests, and in disease it is during the earlier stages, before it has got a big hold on the crop, that it can be most hopefully combated. Other diseases have made their appearance. Pink-rot, which spread with terrible rapidity, and almost threatened the very existence of the industry itself in some districts, was only got under control when the source of the virulent infection was discovered, by the efforts of Brooks, Sharples, and others. Root-collar disease has likewise proved a dangerous pest, but now that its life-history and its mode of attack are understood, it should also become amenable to control. The more recent onslaught of *Phytophthora*—akin to the potato blight at home, and especially in its ruthlessness—is giving trouble, especially in Malay, where it has recently appeared. A similar, and perhaps identical species, investigated by Petch, has been known for some years in Ceylon, where, however, it does not appear to be especially dangerous. But it must be borne in mind that it by no means follows that a disease which is virulent or mild in one climate or soil will necessarily preserve the same characters in regions where the physical or climatal conditions are different. The *Phytophthora* will need careful watching, especially in continuously damp climates.

It is not in the slightest degree probable that the planter will have peace from the attacks of fresh, and as yet unknown, pests. The history of plant pathology contains many records of fungi and other organisms which, from apparently relatively harmless antecedents, break out as violent parasites, whenever they find suitable host plants, which are constitutionally unable to keep them at bay. It must be remembered that these lower organisms produce countless hordes of spores or germs, which are, moreover, easily distributed very widely, and if

any of them happen to fall on an appropriate nidus, such as a suitable plant not specially protected, they will almost inevitably force an entrance with, it may be, disastrous results if timely measures are neglected.

Now, the rubber tree (*Hevea*) is not indigenous in the East, and we may take it as quite certain that there are many fungi and similar organisms, to say nothing of insects, against which it has no immunity, and to which, when the opportunity arrives, it will fall a prey unless extraneous and effective help is given. And in all these matters there is no time to waste in blind empirical trial. What is wanted is the very best advice that can be obtained, and it ought to be available at once. The proverbial stitch in time is likely to be worth, not nine only, but ninety-nine.

In the West Indies, where the planting of *Hevea* has, save in a very few estates, hardly got beyond the experimental stage, there has been but little trouble as yet. But the history of every new tropical enterprise is much the same in this respect, and the West Indian, like the Eastern planters, are likely to have enough on their hands. The case of sugar will not be forgotten by the enlightened body of men who are advising the West Indian estates.

But whilst the problems of dealing with diseases have imposed, and will continue to impose, upon any planting community the need of maintaining a scientific staff to look after the sanitation of the trees, even if it is only urged thereto by elementary considerations of common prudence, there are other aspects of scientific assistance which ought not to be lost sight of, as they are rather apt to be so long as the necessity seems less stringent.

There remains much still to be learnt about such relatively simple matters as tapping the trees. Parkin made a notable discovery when he established the existence of the wound response; and others, by anatomical investigations, have shown that the laticiferous system of tubes does not run vertically but spirally in the tree. This has given an important clue to a rational method of arranging the cut. But these things are, after all, only on the fringe of infinitely more important problems which ought to be seriously tackled, as they would have been tackled long ago if the leaders of the rubber enterprise had fully understood the power which a scientific knowledge of their living machinery is able to place in their hands. These all-important matters which I now have in mind may be shortly stated to be, first, the physiological significance of the production of rubber and its chemical antecedents, not to the *planter*, but to the *plant*; and, secondly, those scientific investigations which are conveniently summed up in terms of stock-breeding. Now these are large matters, and before they can be brought within the tangible reach of practice, a good deal of what is sometimes called pure science will have to be invoked. One is liable, when urging an embarkation on a research conducted without any *immediate* practical object in sight, to be reminded that the practical man is out to make money, and not to subsidise pure scientific research, which does not obviously or directly contribute to this result. This attitude is largely due to a misapprehension of the methods of science. In the larger affairs of life and business, it is not a paying or long-sighted practical policy to condemn the expenditure of every sixpence on Monday which fails to yield an obvious shilling on Tuesday. Still less is it a far-sighted view that nothing is likely to matter much to a concern, even one in which large risks are taken, because it has hitherto been able to pay a big dividend. What does matter is the establishment of a sound policy while business is good, and the furthering of future interests while things are still going well. Hard times and the stress of competition will come to rubber as to other industries, quite apart from the present difficulties. And one of the sides from which the attack is bound to be delivered is the chemical one.

Now chemistry has served the industry fairly well so far. The different coagulation methods, vulcanisation,* and various other ways of dealing with the latex and its products, have formed essential stages in the successful development of the industry as a whole. But chemistry is a two-edged blade, and when synthetic rubber begins to loom seriously in the future as a commercial proposition what will the British planters, and the shareholders in the plantations, have to say to it? At any rate they have done practically nothing to forestall it up to the present time.† Although the matter is attracting some attention in the circles that largely control the industry, there is little evidence at present of any adequate appreciation of the real

* Plantation rubber still needs much chemical investigation in order to perfect its most profitable vulcanisation.

† An American combine in East Sumatra is doing, with characteristic thoroughness, far more than the British organisations. They employ a staff that is both adequate and well paid, and will certainly reap a well-deserved profit.

nature of the task with which they are confronted. It is not, of course, unlikely that some improvement may be effected by mere empirical selection, whether of cuttings or by seed. But it is well known that there are rather special difficulties in the way, quite apart from all questions of influencing resistance to disease. For example, a tree may yield well for a time, and then fall off, only to become a good yielder later on. Others again behave differently, and are regularly either good or bad. But these facts evidently afford important clues to profitable lines of investigations in the future. Meantime breeding work is being conducted in Ceylon and perhaps elsewhere—a beginning has been made in a very small way at Singapore—on an altogether preposterously inadequate scale.

Furthermore, unless breeding operations are placed under the direction of men who thoroughly understand what they are about, and who are aware of the great complexity of the problem, the money and time expended will almost certainly be thrown away.

Breeding experiments are hardly likely to be of much value if they are confined to empirical and haphazard lines. A well-staffed and well-equipped experimental station and laboratories, devoted to breeding and kindred problems, ought to be provided in each of the main rubber-growing regions, and there ought also to be a settled policy of research. And by research I do not mean a concentrated effort to grasp at once at practical results, but to acquire knowledge—knowledge which when properly utilised will pay well. It is no use expecting to get big results in a few years, and hence the stations must be placed on a practically permanent basis. Nor is much likely to come from an establishment in which only breeding, in its narrower sense, is conducted, and it is but fair to put this aspect of the case forward. I suppose if one were to ask a planter what he expects to get out of the money devoted to maintain a breeding institute, the answer would be, Better yield, and a stock more immune from disease. This latter point is, however, fraught with especial difficulties, particularly if it has to be (as it should) combined with increased yield. For a moment's reflection will show that diseases are many, and their modes of attack diverse. Hence it is not at all probable that we shall ever raise a stock capable of withstanding all pests, although it may well be that resistance to some will prove to be quite within our power. Nor is any full measure of reward likely to accrue from breeding for yield, until we know something definite about the factors of which yield of caoutchouc is an outcome. But please do not think I take a gloomy view of future possibilities. The possibilities are great, but they will only be realised if we set about intelligently to make them materialise. We shall want, to begin with, real and accurate knowledge as to the significance of rubber and its chemical precursors in the tree. This will give us a genuine basis on which to go ahead, for it will afford clues which are as important from a breeding point of view as they are from a cultural one. In other words, we shall have begun to dissect the big complex problem into smaller ones, for which we may hope sooner or later to discover the solutions. But the sort of knowledge required is not mere speculation, such as whether the use of the latex is to heal wounds, or render the plant distasteful to animals, or any of those other functions which idle and rather childish guesses have suggested for it. We want to know precisely what is its physiological meaning, and all about its actual formation, and then we may hope to realise and control the conditions that make for its production within the plant. That it is related to the carbohydrate metabolism is certain, and that it stands in some sort of connection with resin is also pretty clear. And this last is a point of special interest, inasmuch as resins are present as more or less of a nuisance in all latices. The problem is not a simple one. Its solution may well tax the brains of the ablest men. But without doubt it ought to be taken seriously in hand, and that with as little delay as possible, for it is of really first-rate importance. It may be that the full solution is still far off, but the knowledge gleaned by the way is certain to repay the outlay—but only on one condition, that really able and well-trained men are engaged upon it. Anything else will be merely throwing time and money away.

Another set of problems will have to claim the attention not of rubber-planters only, but tropical agriculturists generally. In Europe and America the soil has, for some years, been looming ever larger in the minds of far-sighted men who are directing the higher agricultural practice. With more intensive cultivation, and the much greater yield arising therefrom, the soil has had to be investigated from the chemical, physical, and the biological points of view. The upshot of the whole matter has been to emphasise the unexpected importance of the biological aspect of the case. The fungal flora

and the micro-organisms of both animal and vegetable nature exercise an immense influence on the fertility or otherwise of the soil.

In the tropics the soil problems are bound to call for a far greater share of attention than they have hitherto received. In Ceylon, for example, it is generally recognised that there are difficulties in replanting estates. The action of the sun and rains on the land tends to destroy its fertility, partly by the mere physical action of removal, but partly also by the prejudicial effects of direct sunlight on the soil. The problems are not quite identical with those that are before us in the temperate climates, but they are not less important if we desire not only to increase, but even to conserve the capital value of the land.*

I have endeavoured to indicate very briefly some of the main directions in which science has aided, and in which it can further aid the great tropical plantation industry. I have also attempted to point out some of the chief difficulties that lie in the way of rapid results, because expectations unduly aroused are apt to be followed by correspondingly unfounded depression if not by irritation. It now remains for me to venture to suggest certain quite general lines on which this assistance, so essential to the well-being of the planting industry, might be most usefully increased and organised.

It must, I think, be clear to anyone who has watched the progress of most of our great commercial enterprises, that one of the commonest causes of arrest or decline lies in a certain lack of imagination which seems to be one of our national defects. The bird in the hand is really not always worth two in the bush, but we are rather too apt to grudge expenditure which gives no immediate promise of a tangible return. Our attitude to so-called "applied science" affords an illustration of this. Thus, when we have grasped the fact that we require scientific assistance to enable us to cope with the natural difficulties of disease and so on, we get out our mycologists, chemists, entomologists and what not, and then set them down mainly to do routine work—to deal with current difficulties only. No serious attempt is made to tackle the really big problems. We have, as I have already remarked, no adequate establishments to deal with the important matter of breeding. It is true that Ceylon has advanced a little—a very little—way in this direction. But it is quite certain that nothing very much can reasonably be expected to come of it on the present lines. Provision in the tropics should be made for such work on a liberal scale, and there ought to be no question of a five or ten years' scheme, but it will have to be secured on a permanent basis if any real good is to come of it. A well-staffed and well-found establishment will certainly, in the long run, repay all the expenditure many times over, but results of immediate practical value are not likely to come in this or next year, nor ought they to be expected or demanded.

This is perhaps not the occasion on which to raise or to discuss details of high policy, but in general terms it is safe to say that the matter ought to be taken in hand by the governments specially concerned, and administered by a body on which the planting industry, and also the relevant branches of science, are properly represented. Such a combination of official, practical, and scientific men ought to be able to ensure that the work would be carried out on well-considered lines. The three lines of interests, if I may use such a term, would view the matter from different angles, and although there might be differences of opinion as regards details, the general outcome of such co-operation should make for real efficiency. But, as I have already said, it would be essential that the enterprise should be definitely freed from the start from all demands for early practical results. And furthermore, when once the general lines have been laid down, and good men have been secured, those responsible for conducting the experiments must be given as free a hand as possible—and the less said about time-limits the better.

I believe it would be of great advantage if a suitably constituted committee were formed to serve in this country in connection with any such schemes. The functions of such a committee evidently should not be administrative, otherwise friction would almost certainly arise, and it might seriously impede the usefulness of an institute working in a distant country and confronted with conditions that might be imperfectly understood by persons living at home, and unfamiliar with local circumstances. But a home committee, charged with advisory functions only, would serve the useful purpose of bringing the tropical institutes into direct contact with the clearing-house of European knowledge, both economic and scientific. From the latter point of view at any rate, such a connection would seem to be eminently desirable,

* The American combine already alluded to have a soil-chemist on their scientific staff.

inasmuch as the results of the rapid advances which are being made in scientific knowledge and outlook would thus be rendered easily and naturally available to those engaged on the more specialised work of the institute or institutes. And such an association or committee, by furthering the aims and objects of the several institutes that may be brought into being, could not fail to react beneficially on the planting industry as a whole. Its efforts should be the more acceptable since matters affecting individual trade interests would lie entirely outside the terms of its reference.

The germs from which such organised institutes as I have indicated might be developed, are already in existence in the various agricultural departments of Colonial Governments, while influential bodies of men interested in the plantations have shown that they take an enlightened view of the situation. Notably, the Rubber Growers' Association, the Malay Planters' Association, and the Ceylon Planters' Association have exhibited a readiness to avail themselves of scientific assistance, and at their own cost. If they so chose, they obviously could do much, both by influence and material support, to promote the establishment of real research institutes, just as they have already done in securing what may be termed *ad hoc* scientific help.

Of course the scheme would cost money, but the expense would be very small in comparison with the magnitude of the interests at stake. At the present time, in the Middle East, if one takes the total proportion of revenue from the government and planting sources that can fairly be charged to expenditure on science in rubber production, it only amounts to a few thousands (say £12,000) per annum. The estimated value of the last year's crop is about £50,000,000 sterling. In round numbers this means less than sixpence per £100, but even of this only a small fraction is spent on research and investigation. Put in another way, the cost of science, as actually and directly provided by the industry itself, has been calculated to be about equivalent to the hooping used for binding the cases in which the rubber itself is exported. This scarcely strikes one as an adequate proportion to spend by way of insurance on the only effective means of combating disease, and of forestalling chemical synthesis.

To sum up then, science has been invaluable in the service of the rubber plantation industry, both from the chemical and also, and especially, from the biological side. If the industry is to continue to prosper, it has become essential that the investigations of disease and immunity, of the mode and significance of the latex and its constituents within the tree, as well as of the breeding of better stock, shall not only be maintained at their present level, but considerably increased. A distinction will have to be drawn between the necessary routine, *i.e.* scientific sanitation and inspection work on the plantations, and the research work largely to be carried on in the institutes. Both are essential, if the true interests of the rubber-planting enterprise and its future growth and prosperity are to be adequately safeguarded.

There are many other aspects of the services of science to the rubber industry which I might have developed, but as I had to make a choice I have selected those which seem to me to be of the most cardinal importance to the industry as a whole. I am aware that a considerably increased interest in scientific research is now being entertained in influential quarters, an interest which, one may be permitted to hope, will shortly become apparent in its effects. Meanwhile no one with a knowledge of the facts can doubt that, given a proper co-operation of science with practice, a larger—a much larger—return of rubber per acre is possible, and that this will be one of the most effective means of enabling the plantations to hold their own against competition and danger, whether from the synthetic factory or from other sources.

DISCUSSION.

The Chairman (Sir Edward Rosling) said it was over thirty years ago, about the time when he started tea-planting, that the first few rubber trees, the early descendants of those plants imported by Mr. Wickham into Ceylon, were being planted out in cocoa and tea estates, purely in an experimental way. He agreed with the author that true research was often apt to be starved by the desire for immediate results, as was only natural when men were dealing with a subject by which they had to earn their living. On the other hand, he thought the author had hardly done justice to those planters and others who had endeavoured to provide that research work. The rubber-growing industry, from a commercial point of view, could only be said to date from 1905 or 1906, and as far back as 1909 two research schemes were initiated, one under the auspices of the Rubber-Growers' Association and the other by the Planters' Association of Ceylon in conjunction with the Ceylon Government and the Imperial Institute. Those schemes were developing on more or less normal lines, the aim being to combine research proper with the correct balance

between the pursuit of immediate results and scientific research, when the war broke out and hindered all development on those lines. At the present time negotiations were proceeding with a view to co-ordinating existing research schemes in Malay, Ceylon and the Straits Settlements, and if those proposals materialised they ought to afford the means for carrying out research proper side by side with investigations on subjects of more immediate importance, such as disease. When it was realised that our knowledge of the rubber tree was so limited that no one could even hazard a guess of what the maximum yield from any tree would be when it was thirty years old, it would be seen what a very lengthy and complex question the subject of breeding for yield must be. Work of that kind could not be started for one year or five years: if the question of breeding for yield was to be undertaken properly, continuity of action must be ensured for anything from a quarter to half a century. At the present time there was an American combine carrying out most useful and up-to-date scientific work in East Sumatra. The combine was particularly fortunately situated in that it was self-contained, utilising its own products in its own factories, and having control of very large financial resources. The chief difficulty in dealing with research had been in co-ordinating and directing in a general way the work of the scientist in the East, and more especially in securing the right type of men with the right kind of training. Personally he was very hopeful with regard to the future, and it was a very happy augury that such an eminent scientist as the author should have given the careful thought to the subject which had been evidenced in the paper.

PROFESSOR WILLIAM BATESON, F.R.S., said the only aspect of the subject with which he had any special acquaintance was the question of breeding. He was very glad indeed to hear the author lay so much stress on that aspect, and felt sure that he was quite justified in looking forward to great results from the application of proper breeding science to the rubber industry. When returning home from the meeting of the British Association in Australia he visited a rubber plantation at Singapore, and it had always been clear to him since that time that rubber was a plant which was crying out for the scientific plant-breeder. At the present time the trees were grown from seed, and were then planted out in parts of the jungle cleared for the purpose, and when they were about six years old—that was to say, old enough to produce rubber—they were distanced from each other about 20 or 30 feet, so that each tree occupied a space of about 400 square feet; and it obviously mattered very much whether the tree was a good yielder or an inferior yielder, because it took the same amount of labour and space, although the produce might be very different. He had no doubt that trouble would be experienced owing to fluctuations with age and other conditions, but it should be possible for a person conversant with plant-breeding to exclude sources of error in practice. He had also seen the experiments going on in Singapore, and, although great pains were taken with them, they were carried out by men over-burdened with other work and without any special acquaintance with plant-breeding, and it would not be surprising if they met with comparatively little success. In one place he found that the seed was collected from the best trees, but no attention had been paid to the question of paternity. It would be very easy in the case of flowers like those of *Hevea* to conduct artificial fertilisation, and to ensure that the seeds were the produce of good trees on both the father's and mother's side. The question of breeding was a fundamental one, and it had to be brought home to those who had no personal experience of it that rubber trees were just like so many apple trees and crab-apple trees growing side by side in an orchard; and if rubber-growers were dependent on seed, as apparently the *Hevea* industry was at present, they were certain to be sowing trees of every kind of quality, whereas with comparatively little effort it should be possible to have all the trees good ones, as had been done in the case of other plants, such as the sugar-beet. He could not understand why rubber-growers did not propagate fine trees in the ordinary way in which fine trees were propagated, multiplying, by cuttings or in other ways, the best existing plants. Some difficulty appeared to have been experienced in propagating the rubber plant, and he would like to ask what the difficulty was that prevented fine rubber trees being propagated, and caused planters to rely entirely upon seed. He thought that in the case of tropical products, such as rubber and jute, when proper breeding was applied, as it certainly would be in the future, changes of the most extraordinary description might be anticipated.

PROFESSOR H. E. ARMSTRONG, F.R.S., said that, on his way home from Australia, he visited Ceylon largely with a desire to learn as much as he could of the rubber industry, and although the time he had was very brief he managed to see a good deal of it. He felt that no adequate scientific attention had been paid to the industry in order to solve the many problems that had to be considered. When one recollected what had been the history of cinchona and coffee in Ceylon, for example, one felt rather suspicious that something of the same kind might happen to rubber, and that it might fall a victim to disease in the same way that coffee did. In the case of cinchona, the industry had been lost because proper attention had not been paid to its development; but in the case of coffee the decay of the industry was due to the action of a fungus. From what he had learned in Ceylon he rather thought that a good deal was done in advance to prepare the way for the fungus. During the past three years he had been directly connected with the efforts that had been made for the resuscitation of the indigo industry in India, and the principal difficulty experienced in that direction was an agricultural

difficulty. It was difficult to get a crop, and it was impossible to raise seed in certain important areas. The reason why a crop could not be obtained was that there was phosphatic starvation of the soil, which had so small a quantity of phosphoric acid that the plants would not grow. When phosphatic manure was applied a good crop and good seed were obtained. One point that struck him very much in Ceylon was the absence of phosphates in the soil, and he was inclined to think that the way was prepared for disease in the coffee plant by that absence of phosphates. The same kind of thing was very likely to happen in the case of rubber, and there might be a sudden failure of the rubber crop in years to come when the phosphates in the soil had been worked out. The primary point that required special consideration in Ceylon was the question of the mineral content of the soil. The same thing occurred in Australia, where in many areas wheat crops could not be grown because the amount of phosphate was below the necessary minimum, and phosphates had to be put on the soil in order to obtain any crop. He was so impressed by the situation that when he was in Colombo he wrote a letter to the *Times of Ceylon*, in which he drew special attention to the point, and said that he could not discover that planters were in any way alive to the need of placing their industry on a scientific footing at all comparable to that on which the manufacture of dye-stuffs in Germany had long stood. The few isolated scientific workers on plantations had their hands too full of routine work to carry out the preliminary inquiries that were necessary, and the services of a staff of highly-trained and competent men were required. He made the suggestion that the Government should intervene, and levy an insurance tax of a halfpenny per pound upon all rubber estates in British possessions, but that scientific investigations should be carried out under the supervision of those engaged in the industry, the task of the Government being that of enforcing an adequate scientific inquiry. If the amount so raised were devoted to scientific inquiry in connection with the rubber industry, it would be a small sum to pay for insurance, and would lead to a very great development of the industry. He still thought that some such measure as that must be adopted. It was no use leaving the matter to private enterprise in the first instance; the State must enforce a proper measure of scientific inquiry being taken without loss of time.

Mr. Herbert Wright thought that any money spent on investigating disease in the rubber plant meant making more money, and that very rapidly. Very few people realised how the British people had acted as pioneers in connection with the plantation industry. There were something like two million acres of rubber in the world, and British people owned approximately 75 per cent. of that acreage—in other words, they owned 1,500,000 acres of rubber. It was difficult to forecast the yield from rubber trees, but he thought that ultimately, subject to labour and diseases permitting, British interests in plantation rubber were likely to yield approximately 250,000 tons of rubber annually. If that rubber was valued at pre-war prices, about £300 per ton, it would be seen that British people owned plantations which could produce annually rubber valued at £75,000,000. If two-fifths of that revenue come to this country for taxation purposes, it would yield a sum of £30,000,000 annually, and that showed that the plantation industry was a real asset to the British Empire. Every tree saved from disease meant more produce, more employment for British people, and more revenue for Great Britain. He hoped that every endeavour would be made to improve the plantations already established, and that rubber-growers would not rest content with the work that had been accomplished. With regard to diseases something had already been done, but, in his opinion, not nearly enough. Even some directors of rubber companies, and certainly many investors, would be very much surprised to know the extent to which the various parasites affecting the roots and bark of rubber trees had taken hold of plantations. The number of scientific officers engaged in mycological work in the tropics was very small. There was not one mycologist even for 100,000 acres of British-owned rubber, and that meant that there was not one mycologist even to attend to a property worth £10,000,000. Almost every mycologist in the East had been trained under the author's direction or had come under his influence in some way, and the author would agree that every mycologist in the East had far more work put upon him than he could possibly carry out. If diseases overtook rubber plantations in the East the responsibility would not be upon the mycologists but upon directors of companies and scientific institutes. In pre-war days it was impossible to find in this country men fully trained to carry out the necessary research in mycology in the East. He had sent many men to the East in connection with research work, and especially in connection with fungi, and in some cases he had had to send men to Germany to complete their education. Since one or two years before the war, however, it had been possible to train and equip men at the Imperial College of Science quite as well as they could be trained and equipped in Germany. Professor Farmer had made the mycological department of the Imperial College second to none in Europe, and the least that directors of plantation companies could do was to take his men as soon as he pronounced them competent. The future of the rubber-planting industry depended mainly on the overcoming of disease, and if the subject was not approached in a very bold and generous spirit an industry would be lost which was of real value to the Empire.

Captain A. W. Hill (Assistant Director, Royal Gardens, Kew) said that an important factor in connection with rubber plantations in the East

was the question of the seed from which the plants had been grown. When there was a boom in rubber-planting a few years ago there was a great desire to get seed and to start plantations. Seed was taken from wherever it could be obtained, and it might very probably be found to be the case that plants which yielded seed quickly were not necessarily plants which yielded the greatest quantity of rubber. There must be a very large number of plantations made up of trees grown from seed which nobody knew anything about. Again, it was very often thought that if a certain number of trees on a certain acreage produced a certain yield, twice that number would produce double that yield. That was an idea very prevalent in plantations on the Gold Coast, with lamentable results, and he thought there were estates in the East where the same opinion was held. With regard to the cuttings referred to by Professor Bateson, in the early days they were made at Kew with some success, after the practicability of this method of propagation had been demonstrated at Calcutta. Probably the rubber tree was one of those plants from which cuttings had to be taken at a special time of the year in order to be successful; but he thought that the reason why people had not troubled very much about cuttings was because of the great ease in obtaining seed and its good germinating qualities.

Mr. H. A. Wickham said he had been instrumental in the introduction of the rubber tree to the East from the Western tropics. He thought the fact had been overlooked that the rubber tree was a large forest tree, and it had been up to the present day and still was altogether too closely planted. Rubber estates had been looked on too much in the light of tea estates or coffee estates, instead of being treated on forestry lines. In his original report to the Government of India he suggested that a tree of the order and habits of growth of the rubber tree should not have been given a less spacing than half a chain, *i.e.* 33 feet. As a matter of fact, they were standing in various spaces at a distance of 12 feet or 15 feet apart, and under those conditions they never had a fair opportunity to develop. With regard to systematic clean cultivation, constant hoeing and forking had caused the surface soil to be drained into the rivers and so carried away, and he had come across places in Ceylon where one could actually pass one's arm underneath the roots of the trees. From his experience of similar cultivation—for instance, the cultivation of the chocolate tree—he could say that if the soil was kept heavily mulched the yield could be doubled. One had to aim at forest conditions, and conserve the surface of the soil. If the surface soil was kept covered by a heavy mulch it became mainly formed of the intestinal castings of earthworms, and the soil underneath the mulch was perpetually moist and resembled garden mould. The great point for the practical planter was to keep his trees in good health, and that could be done by approximating to their natural requirements and conditions as nearly as possible. He had been watching the industry for many years, and he thought the yield per acre obtained at present was not as great as it ought to be. Taking 350 lb. as the average yield per acre, he thought that was only about one-third of what the yield ought to be at the present day. With regard to rubber-curing, in his original report he suggested that the basis of starting curing should be taken from the standard rubber of the day, namely, hard-cured. His suggestion was put on one side as empirical, and the consequence was that the industry had now become standardised into two distinct markets. There was the plantation rubber sold as plantation rubber, and the hard-cured sold as hard-cured. He fully appreciated the value of science, but he did not think that science and empirical knowledge in any way clashed, and he thought the evidence derived from experience was of very great value.

The Chairman, in reply to Professor Bateson, said that no difficulty had been experienced with regard to cuttings from plants imported by Mr. Wickham in Ceylon, and he thought the chief reason why seed had been used to such a large extent was that there was no direct evidence of a great variation of yield amongst different trees, so that there did not appear to be any special advantage in propagating by cuttings. That did not bear on the scientific breeding of trees, which undoubtedly there would be great room for when further scientific research had been carried out in the matter. He thought industrial research might be defined as the proper balance between research proper and the pursuit of immediate or early results.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

Professor W. Bateson writes as follows:—At the close of the meeting the Chairman, Sir Edward Rosling, declared that there was no direct evidence of great variation in yield of individual rubber trees, and that practical men did not, as a matter of fact, find such differences. In speaking of *Hevea* trees as differing greatly in yield I had in mind not merely verbal reports of persons familiar with rubber-growing, but several precise records of which the following are examples. W. H. Johnson, "Culture and Preparation of Para Rubber," 1909, p. 27, states that "the yield of rubber from different trees growing under similar conditions in the same plantation varies to an enormous extent." He then quotes experiments of Vernet (*Jour. d'Agric. Tropicale*, 1907), which gave differences ranging between the following extremes: in volume of latex from 4 to 48; in percentage caoutchouc from 29·23 to 39·74; in weight of dry rubber from 1·286 to 14·164. R. H. Lock, "Rubber and Rubber-Planting," 1913, p. 74, writes: "It is well known that rubber trees possess marked individuality as regards the amount of latex which can be drawn

from them. Tapping coolies, if left to themselves, soon discover these differences and confine their attention to the best yielding trees....Among a group of 29 trees of uniform age tapped daily, the highest and lowest average yields for the first 30 tappings were respectively 166 and 8 cubic centimetres. The circumference of these two trees was 52 and 32 in. respectively and they were not the largest and smallest trees in the group. The yield per inch of bark removed was in the ratio of 317 to 25, or more than 12 to 1." Lock adds that in Java the proportion of alkaloid in the bark of the introduced cinchona plants has been nearly doubled by careful selection, and that the variation in yield of *Hevea* is considerably greater than this. He strongly urges a rigorous seed-selection. There is plenty of further evidence to the same effect. Pending breeding experiments, the best trees should at once be propagated vegetatively. Though at Peradeniya only one cutting succeeded out of 3,000 (Johnson, p. 31), I have no doubt that with a little experimenting this difficulty could be overcome. In England *Hevea* strikes easily enough.

GENERAL NOTES.

Japanese Clock Industry.—The value of the clocks annually exported by Japan previous to the war was from 700,000 yen to 800,000 yen. Of recent years, the British Commercial Attaché at Yokohama states, the volume of exports has increased as the supply of German clocks was cut off, and in 1916 exports in this line from Japan were valued at 1,180,000 yen. During the last three and a half years Japanese clocks have been exported not only to China, the Straits Settlements, the South Sea Islands, and India, but even to the United Kingdom, France, and Italy, and it is believed that some portion of this new trade will be retained after the war. Latterly, however, clockmakers in Japan have experienced great difficulty in obtaining springs, and this has had a very adverse effect upon the trade.

The Oil-seed Industry of Rhodesia.—In view of the fact that even before the war it was becoming difficult to cope with the world's demand for oils and fats for the manufacture of margarine, and that this difficulty has been increased during the war, it is interesting to note that the cultivation of oil-seeds promises to become an important industry in Rhodesia. At present ground-nuts and sunflower seed are the only oil-seeds produced commercially, but experiments conducted at the agricultural experiment stations indicate that other oil-seeds may be grown successfully. Castor seed, sunflower seed, sesame seed, and linseed, grown at the Government Experimental Gardens in Northern Rhodesia, have recently been received at the Imperial Institute, and the results of examination in the Institute's laboratories are given in the new number of the Institute's *Bulletin*. The samples were entirely satisfactory. Before the war, sesame seed was chiefly crushed on the Continent, owing to the fact that in several Continental countries the inclusion of a certain quantity of sesame oil in margarine was compulsory, in order to facilitate detection of the margarine when used to adulterate butter. This factor raised the price of sesame seed, with the result that British margarine makers used other cheaper and equally good oils. Sesame seed is, however, now being crushed in this country—to which the Rhodesian seed will no doubt come after the war—and its use will be continued and extended for the manufacture of edible fats if the price of the seed remains at about the same level as that of other oil seeds.

Pusa Wheats.—Mr. J. MacKenna, C.I.E., Agricultural Adviser to the Government of India, in the paper on "Scientific Agriculture in India" that he contributed to the Society two years ago, said that a safe estimate of the gain to Indian wheat-growers, if all seed sown were of varieties like Pusa No. 12 would, it was calculated, be Rs. 15 per acre per year. The annual report on the progress of agriculture in India shows that through the medium of Pusa No. 12 the cultivators of certain districts of the Punjab and the United Provinces have increased their outturn by 25 per cent., while "Punjab 11" is expected to yield an additional income of at least Rs. 2 lakhs in the year to the cultivators of the 97,000 acres on which it was sown. In the Central Provinces, again, the 200,000 acres under various types of Pusa seed are bringing in an additional income of from Rs. 10 to Rs. 20 lakhs annually. We are told that Mr. and Mrs. Howard, whose experiments in cross-breeding wheat are so well known, believe that the present varieties are not "the last word," and that they will shortly be in a position to give the cultivator something even better. "When it is borne in mind that the area under wheat in the year under report amounted to nearly 33,000,000 acres, the possibilities here," says the *Pioneer Mail*, "are readily apparent."

Production of Steel Plates in Australia.—It is reported by the *Australian Industrial and Mining Standard* that steel plates have been produced for the first time in Australia at the Broken Hill Pty. Co.'s Steel Works at Newcastle. Two hundred tons of plate, 12 ft. and 22 ft. long, varying in thickness from half an inch upwards, are said to have been rolled in the four weeks ended February 6th. Some further modifications in the equipment are necessary, and these are being effected. The rolling of these plates will, it is believed, make it possible to build steamers in Australia constructed entirely of materials manufactured in the Commonwealth.

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2.

Registered as a Newspaper.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi London, W.C. (2).

Journal of the Royal Society of Arts.

FRIDAY, JUNE 28, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The One Hundred and Sixty-fourth Annual General Meeting for receiving the Report of the Council, and the Treasurers' Statement of Receipts and Payments during the past year, and also for the Election of Officers and New Fellows, was held in accordance with the By-laws on Wednesday last, June 26th, at 4 p.m., Mr. ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, in the chair.

The Secretary read the notice convening the meeting, and the Minutes of the last Annual Meeting.

The following candidates were proposed, balloted for, and duly elected Fellows of the Society:—

Basden, Duncan Frederick, London.
Bowie, James, Messrs. Parry & Co., Calcutta.
Brain, Henry Richard, London.
Bramwell, Samuel, J.P., Tunbridge Wells.
Brassey, Earl, D.C.L., London.
Breidenbach, Reginald Blackwell, East Croydon.
Chreiman, Miss Mary A., London.
Day, Charles, M.Sc., M.I.Mech.E., M.I.E.E., Stockport.
de Segundo, Edward Carstensen, A.M.Inst.C.E., M.I.Mech.E., London.
Dinsmore, John, Ballymena, Ireland.
Drake, William Armitage, Halifax, Yorks.
Flather, David, Sheffield.
Forbes, David MacHattie, Hawaii.
Garnett, George, Bradford, Yorks.
Hatchard-Smith, John, London.
Highfield, John Somerville, M.Inst.C.E., M.I.E.E., London.
Howard, Alexander Liddon, Totteridge.
Johnson, Hubert, Hull.
Khoo Sian Ewe, Penang, Straits Settlements.
Lamplough, Frederick, M.I.A.E., Feltham.
Liversidge, Engineer-Captain Edward William, R.N., Bermuda.
Low, Henry, Assoc.I.Min.E., London.
Major, John Lewis, London.
Matthews, Lieut. Frederic, Colchester.
Mhatre, Succaram Vassudeo, Bombay.
Mitchell, Harry, London.
Mitchell, Walter Ashby, Dundee.
Nichols, Ernest George, Manchester.
Owen, Councillor Evan, J.P., Cardiff.
Parlakimedi, The Raja of (Sri Sri Sri Krishna Chendra Gajapati Narayana Deo), Ganjam District, India.
Parshall, Horace Field, D.Sc., M.Inst.C.E., London.
Parsons, Charles Frederick, London.
Paul, William Hewitt, Birkenhead.
Perrott, Wilkinson Kidd, London.
Poulter, Captain Herbert William, Baghdad.
Prosser, John, Greenwich.
Richardson, Thomas Augustine, London.
Saklatwalla, B. D., B.Sc., Dr.Ing., Bridgeville, U.S.A.
Shipley, Rev. Samuel Paul, F.R.Met.Soc., Oakham.
Snow, Ralph George, Woldingham, Surrey.
Snow, William Ralph, London.
Strachan, Gilbert Innes, M.D., Cardiff.
Symington, William, Bickley, Kent.
Taylor, Charles Wardrope, South Shields.
Tooth, W. E., Burton-on-Trent.
Turner, William Lourence, Caldy, Cheshire.
Ung, B. H., B.Sc., Penang, Straits Settlements.
Vyle, Gilbert Christopher, Birmingham.
Wall, R. Howard, Chigwell, Essex.
Walters, Colonel Herbert A., V.D., Bromley, Kent.
Wisnom, Engineer-Commander William McKee, R.N., Dumbarton.
Wolseley, William Augustus, London.
Wordingham, Charles Henry, C.B.E., M.Inst.C.E., M.I.Mech.E., M.I.E.E., Redhill.

The Chairman appointed Mr. Denis R. Broadbent and Mr. Henry Hill scrutineers, and declared the ballot open.

The SECRETARY then read the following—

REPORT OF COUNCIL.

At the end of the Society's 164th Session the Council are glad to be able to congratulate the Fellows on a successful year's work. The papers read both at the Ordinary Meetings and at the Meetings of the Indian and Colonial Sections have reached a very high standard of excellence, and that they have been appreciated is shown by the fact that the audiences, as a rule, have been large—sometimes crowded—in spite of the pressure of business and the preoccupation which is so general at present. An even more hopeful sign is the increase in the number of new Fellows—which amounts to 373 this year, as compared with 164 in 1917. A pronounced increase has also been made in the entries for the Examinations, this year's total, 31,135, being 4,950 above that of 1917—a result which can hardly be regarded as other than remarkable considering the fact that many who would have been candidates in normal times are now serving in the Army.

I.—ORDINARY MEETINGS.

In his inaugural address, under the title "Science and its Functions," the Chairman (Mr. Alan A. Campbell Swinton) gave a rapid but brilliant review of human progress from its rude beginnings to the present day. In the course of this he showed that scientific research and investigation constitute the soul of industrial progress. Incidentally he brought out very clearly the points of similarity and difference between pure and applied science, and demonstrated, by examples from the history of wireless telegraphy and X-rays, how great discoveries which at first were purely theoretical have led to immense developments of the most practical and utilitarian importance. The address concluded with a plea for a better understanding by our Government Departments of the value of science, and the necessity for promoting its applications to industries; and at the same time a warning against such political interference as had for many years practically stopped the development of the motor-car industry in this country.

The two admirable inaugural addresses delivered by Sir Dugald Clerk in 1915 and 1916 led the Council to invite him to give the first Trueman Wood Lecture,* established in honour of the late Secretary. He selected for his subject "Discovery and Invention," and he gave a most lucid exposition of the essential difference between practical invention and scientific research. His thesis was illustrated by numerous instances from the history of invention, and the lecture must be regarded as a masterly discussion of a difficult and subtle problem.

One of the subjects to which the war has compelled us to give closer attention than in the past is the question of the relations between the State and trade. In order to organise and co-ordinate these relations the Board of Trade have instituted a new Department of Overseas Trade, of which an admirable account was given by its Comptroller-General, Sir William H. Clark. He described various developments which are being now undertaken, including the Trade Commissioner Service, the Commercial Attachés, the Consular Service, the special investigations of overseas markets, the relations between the Department and the commercial community, the methods of distributing information, and the holding of international and sample exhibitions.

Probably no paper read during the session attracted so much attention both within the Society and among the general public as that which Lord Leverhulme gave under the title "'Zero' of Capital and Labour." Dealing first of all with the question of the conscription of wealth, his lordship clearly showed that there is a point beyond which capital cannot be taxed without seriously crippling industry; and with regard to the graduation of income tax and death duties, he laid it down that the only limit is that point at which they yield the largest return to the State with the least injury to our industry. Lord Leverhulme expressed a confident opinion that if the country, as a whole, turned its attention to increasing its production to the extent of which it is capable, it would have little difficulty in clearing off the burden of debt imposed upon it by the war. He also urged the advisability of giving workers a financial interest in their work by means of co-partnership. Coming as it did from a great employer of labour who has tested his theories by wide practical experience, Lord Leverhulme's paper must be looked upon as a pronouncement of the greatest interest.

The relations between Capital and Labour also formed the subject of Mr. A. H. Paterson's paper, "The Foundation of Industrial Peace." Mr. Paterson is the Secretary of the National Alliance of Employers and Employed, a body which aims at establishing the friendliest and

* See also page 509.

closest relations between masters and men by bringing them together to discuss not merely business relations but also any questions in which they are jointly interested, such as housing, education and so forth; and he urged that it is only by the establishment of some such bond as this that we can hope for permanent industrial peace. Taken together, these two papers, with the very interesting discussions which they elicited, may be looked upon as a hopeful sign that the long hostility between employers and employed is drawing to a close, and that each side is beginning to see that its real interests and welfare are bound up in those of the other.

An interesting feature of the sessional programme was a series of papers dealing with the application of science to particular industries. In the first of these Professor J. Wemyss Anderson discussed the problems of the cold-storage industry. He pointed out its great and rapidly increasing developments in connection with meat, fish, poultry, eggs, fruit and cereals, and, in view of the numerous problems awaiting investigation in this connection, he made a strong plea for the establishment of institutes of research and schools of refrigeration in London and Liverpool, and for the provision of facilities for instruction in mechanical refrigeration at the principal technical colleges and schools throughout the country.

In the second paper of this series Dr. Reginald S. Clay, after sketching the history of the British pianoforte industry, described the steps that are at present being taken to improve the quality of British instruments. One of these is the establishment of a kind of hall-mark which should be a guarantee of the quality of a piano bearing it; a second is the standardisation of instruments; a third is the apprenticeship scheme, which is being conducted with good prospects of success under Dr. Clay's supervision at the Northern Polytechnic; and the fourth is the establishment of a school of research in connection with the piano, in which purpose piano manufacturers are co-operating, with the help of the Industrial Research Committee.

A subject of great topical interest was dealt with by Sir George Watson, Chairman of the Maypole Dairy Company, who described the manufacture of margarine in Great Britain. Immense strides have been made during the war, the average weekly quantity of margarine manufactured in this country having risen from 1,611 tons in 1913 to 3,564 tons in 1917. Incidentally a plea was made for linking the interests of employers and employed by means of profit-sharing and co-partnership, and the claims of science were handsomely recognised in the recommendation that in manufactures where chemists were employed they should be given seats on the board of directors.

Dr. W. Lawrence Balls, in an admirable paper, brought out the importance of the application of science to the cotton industry. He selected four examples—the cultivation of pure cotton; the study of the length of staple; the deterioration in the yield of Egyptian cotton; and the possibility of making cotton crop reports and forecasts more accurate and useful. Under each of these heads he showed in a striking manner what advances have been made by the aid of scientific study of the problems involved. In connection with the second head he exhibited a machine invented by himself by which the cotton fibres are mechanically sorted according to length and are then measurable with scientific precision. In the opinion of those present the machine was not only extraordinarily ingenious but also likely to prove of great practical value in the cotton trade.

What science has done, and what it may yet do, for the rubber industry was described by Professor J. Bretland Farmer. It should not be forgotten, he said, that "this great wealth-producing agency in the British Empire was cradled in the scientific nursery at Kew"; and he also referred to various critical stages in the history of the industry when science was called in to investigate and overcome the attacks of various pests which from time to time threatened its very existence. Even now a great deal remains to be learnt about tapping, the breeding of trees, and many other problems. A certain amount is being done in Ceylon and Singapore to provide opportunities for scientific research in connection with the rubber industry, and Professor Farmer suggested the general lines on which such work might be usefully extended and organised.

The immense demand for timber caused by the war has made the question of afforestation as prominent as it was at the close of the eighteenth century when the Society took up the matter, and, by the award of gold and silver medals and pecuniary premiums, was instrumental in encouraging the plantation of considerably more than fifty million trees. The present position of the timber industry was

described in an able paper by Professor Percy Groom. The importance of the problems involved may be gathered from the fact that in 1913 the value of the timber imported into the United Kingdom was over £42,000,000, and there was also consumed a large quantity of native-grown wood. After pointing out the principal steps to be taken to alleviate the threatened shortage in the future by the increased production of softwoods in this country, by afforestation in the British Empire generally, by the partial substitution of hardwoods grown in the British Colonies and Dominions for softwoods imported from foreign countries, and by economy in the use of timber, Professor Groom gave a valuable survey of the fundamental facts and principles that have been elucidated by research, and drew attention to some of the problems calling immediately for solution.

Mr. George Martineau, who may be regarded as the *doyen* of the sugar industry, contributed a valuable paper on "Sugar from Several Points of View." He set himself to show, from the history of sugar during the last sixty years, that nascent industries can be encouraged, research stimulated, and efficiency created, by a rational, well regulated, but moderate stimulus; that preferential treatment in home markets is the best, perhaps the only, way to give real confidence to capital; and that with that confidence, coupled, of course, with favourable natural conditions, British industries will flourish, and may even become capable of satisfying the whole consumption of the Empire.

An eloquent plea for devoting more attention to the study of organic chemistry in this country was made by Dr. M. O. Forster. He contrasted the situation in Germany, where 30 universities and technical high schools possess 157 professors of chemistry, with that in the United Kingdom, where 18 universities and 9 further educational institutions can only boast of 47 professors of chemistry. Moreover, as this disproportion has existed for many years, the present relative positions of the two countries in the matter of chemical achievement is not to be wondered at. The numerous and rapidly increasing applications of organic chemistry to industry were referred to. As a director of British Dyes, Limited, Dr. Forster naturally dwelt more particularly on its relation to the question of synthetic dyes, of the history of which he gave an admirable summary.

Professor Frecheville drew attention to the immense mineral resources within the British Empire which are at present entirely unexploited. In Australia and Canada, in particular, vast spaces remain unexplored, although there is good reason to believe that they abound in minerals. Mining industries have hitherto been left almost entirely to individual enterprise, and it was suggested that in future the Administration, both at home and in the Colonies, should adopt a more active policy in developing their mineral resources. Professor Frecheville also expressed the opinion that a Mineral Resources Bureau, if properly constituted, might play a most important part in such development.

Mr. Alexander Newlands, Engineer-in-chief of the Highland Railway, has devoted a great deal of time and energy to the study of water power in Great Britain, and he read an exhaustive paper on this subject, with special reference to Scotland. The tables published as an appendix show that Scotland possesses about 375,000 h.p. which is readily available, and Mr. Newlands urged its immediate utilisation in order to accelerate our industrial activities after the war.

Agricultural Machinery was the subject of a paper by Mr. F. S. Courtney, Consulting Engineer to the Royal Agricultural Society of England. A comprehensive account was given of most of the agricultural implements in use at the present day, and it was pointed out that in view of the shortage of labour and the necessity for producing home-grown food in greater quantities, the demand for machinery must rapidly increase in the near future. Incidentally, Mr. Courtney referred to the use of electric power for agricultural operations, which he believed would be extensively used before long. He suggested a system of co-operation by districts, and he also proposed that each area should decide on the types of machines which are best suited to their requirements. This would tend to the standardising of the industry, which, among other advantages, would save the manufacturer from the necessity of storing a great variety of spare parts.

Monsieur Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, had already given two admirable lectures in French before the Society. This year he read a remarkable paper in English on Ypres and other Flemish cities. His address was illustrated by a large number of lantern-slides from hitherto unpublished official photographs, which showed in graphic manner the ruin and devastation wrought by the Germans on sacred

and beautiful buildings. The meeting, which was crowded, was rendered memorable by eloquent addresses from the Archbishop of Canterbury and His Excellency the Belgian Minister.

In a long and exhaustive paper Major Sir Robert Armstrong-Jones discussed some of the mental effects of the war—the changes in the national outlook upon many subjects, and the reconstructive reforms that are likely to ensue as results of those changes. Among the various points dealt with were the Church, temperance, the care of child-life, the advances in medicine and surgery, the relations between Capital and Labour, and the amendment of the lunacy and marriage laws. The problems involved in the care and treatment of shell-shocked soldiers have educated public opinion in matters connected with lunacy, and a strong plea was made for the treatment of mental cases in their earlier stages, without first committing the patients to an asylum.

Lord Charnwood's paper on "Technical Training for Disabled Soldiers and Sailors" may be looked upon as complementary to the address given last session, in which Sir Arthur Pearson described the provision made for the treatment of those blinded in the war. Lord Charnwood discussed the steps taken by the Government to offer opportunities for technical training for disabled soldiers and sailors who are able and willing to profit by it, and the provision made for their maintenance during the period of instruction.

The future of aviation, and the use of aircraft for practical commercial purposes, were discussed by Colonel Mervyn O'Gorman. He indicated the lines on which aerial activity may be expected to develop, and the manner in which aeroplanes may soon be utilised for the transport of passengers and mails. He also drew attention to the immediate necessity for drawing up international agreements between ourselves and our Allies regulating air routes, alighting rights, etc.

The food situation in Germany, and the various systems of rationing adopted in that country, were described in a paper by Mr. Percy Shuttlewood, who, as an official of the Ministry of Food, had access to the most authoritative reports on the subject. It is, of course, difficult to get much in the way of reliable statistics from enemy countries, but a survey of the available facts and figures leads to the conclusion that the situation in the countries of the Central Powers is grave enough to be termed critical.

Amid the many subjects directly or indirectly connected with the war and with reconstruction, the artistic side of the Society's work was, perhaps, somewhat neglected this session. The only paper relating to art was by Mr. Maurice B. Adams upon the picturesque in architecture. His general thesis was a plea for simplicity and the adaptation of buildings to the end for which they were intended. Among other points he urged the desirability of employing local materials as far as possible, whereby styles of architecture were obtained which differentiated the work of one part of the country from that of another.

II.—Indian Section.

In the course of the session of 1917–1918 the Indian Section has entered upon its year of jubilee, the earliest meeting having taken place in 1869, a year which marks an event of immense importance to India—the opening of the Suez Canal. It may also be mentioned that for the first time in fifty years all the papers were concerned either with commerce or manufactures, at this moment more urgent than any other subjects within the scope of the Section.

Not the least valuable of the papers dealt with the first half-century of English commerce with India, 1608–1658, and was read by Mr. William Foster, C.I.E., Registrar and Superintendent of Records, India Office.

Previous to the war, two-thirds of India's commercial imports were obtained from the United Kingdom, while less than a quarter of her exports of cotton and other raw material came to this country. European foreign markets took one-third of the exports, and Asiatic countries the remainder. The Continent's share was equally divided between enemy countries and the Allies, but the latter in certain cases made their purchases of Indian produce through Germany or Austria. Two years ago Mr. D. T. Chadwick, I.C.S., now Indian Trade Commissioner in London, and Mr. G. W. Black, the present manager of the Alliance Bank of Simla, were appointed by the Government of India to visit Russia to see whether direct relations could not be completely substituted for enemy intervention, and generally to discover in what fresh ways Indian trade with that country could be opened out. On the completion of their inquiries in Russia, the mission was extended to France and Italy. The hopeful results of the investigations made in the three countries formed the subject of

an excellent paper read by Mr. Chadwick at the opening meeting, held on December 13th, under the chairmanship of the Under-Secretary of State for India, Lord Islington.

That remarkable member of the Parsi community, the late Mr. Jamsetjee Nusservanji Tata, had three chief ambitions in life—the smelting and conversion into steel of the undeveloped iron ore of India; the storage and utilisation of the heavy monsoon rains running to waste on the Western Ghats; and the foundation, on a large scale, of a scientific research laboratory. But he did not live to see the complete realisation of his aims. A very interesting paper on the first of the three projects—the Tata Steel and Iron Works—was read on January 17th by Mr. H. M. Surtees Tuckwell. Later in the session an equally instructive account of the second of the Tata schemes, the hydro-electric installation in the Bombay Presidency—"the finest of its kind in the world," as it has been described by a former Governor of Bombay—formed the principal part of a comprehensive paper by Mr. Alfred Dickinson on "Water Power in India."

A timely and useful contribution to a vitally important discussion, namely, the better utilisation of the Empire's resources in raw materials, was made by Sir Henry Ledgard in an able paper on "The Indian Hide and Leather Trade." Of India's various exports, hides are exceeded in value by only four other commodities, jute, cotton, food grains, and seeds. When war broke out this important Indian trade had passed into German hands. Sir Henry Ledgard made an earnest appeal to the authorities in India and His Majesty's Government to take certain measures indicated by him so as to prevent the possibility of the German monopoly ever being re-established, and to ensure that the industry shall in the future be wholly British and Indian.

At the concluding meeting, on June 20th, a paper by the Hon. Sir Dinshaw E. Wacha, Chairman of the Bombay Millowners' Association, on "Indian Cotton and the Cotton-Mill Industry" was, in the author's absence, read by Sir Charles H. Armstrong. The historical survey with which the paper opened included an interesting description of the old trade routes which in part may be re-established as one result of the military campaign in Mesopotamia. Sir Dinshaw Wacha then reviewed the rise and progress of the Bombay mills, and concluded by discussing the economic situation in view of the position of Japan as a large purchaser of Indian yarn and a keen competitor with Lancashire in the piece-goods markets of India.

III.—Colonial Section.

"Land Settlement within the Empire" was discussed at the opening meeting of this Section on November 28th, in an admirable paper by Lieut.-Colonel the Hon. Sir John McCall, Agent-General for Tasmania. His principal suggestions were that the Mother Country should provide free passages to the Oversea Dominions for desirable would-be settlers, ex-soldiers and others, and finance "co-operative schemes of settlement and public works." Sir John McCall, who was a member of the Committee appointed by the Government last year to inquire into the question of offering men of the fighting services facilities to emigrate after the war, also advocated the formation in this country of a Ministry of Migration.

At the next meeting the industrial resources of the Union of South Africa were reviewed by Mr. C. du Plessis Chiappini, who included in his comprehensive and interesting survey some candid observations on the much discussed question of "trade after the war." Viscount Gladstone, who occupied the chair, said that there is no limit to the development of food exports from South Africa, and another speaker, Baron E. B. d'Erlanger, expressed his confident belief that sooner or later Rhodesia as well as the colonies we have wrenched from German dominion and oppression will form part of the Union.

In a singularly able paper on "British Guiana and the Problem of its Development," Sir Walter Egerton explained why it is that that fertile but insufficiently populated possession is still almost as stagnant as were the West African colonies before Mr. Chamberlain went to the Colonial Office, and pointed out the measures that should be taken, *e.g.* railway construction, etc., to rid the ruling Power of the reproach that after a century's possession of a country equal in extent to Great Britain, only an area less than one-fifth the size of Kent is under cultivation, while most of the remainder is trackless forest and savannah unoccupied except by a few nomadic Red Indians.

A special and successful feature of the preceding session were the respective papers of M. Millet and M. Horn on the African possessions of the two Allies who are our nearest neighbours—France and Belgium. In

the session just concluded the African and other colonies of our oldest Ally, Portugal, were considered. In his attractively-written paper on the subject, Mr. George Young asked and answered the three following questions:—How was the Portuguese colonial power constituted; in what does it consist; and what contribution can it make to our reconstruction of civilisation?

IV.—Cantor Lectures.

Four courses of Cantor Lectures were delivered this session. In the first of these Professor H. C. H. Carpenter dealt with Progress in the Metallurgy of Copper. He gave a brief historical synopsis of the industry in early times, and of its rise and development in Great Britain. Copper-smelting was started in Swansea in 1717, and the industry made great progress in the eighteenth and nineteenth centuries. The conditions which made for this success were carefully analysed, as were also the causes for its subsequent decline. The development of mining and smelting in Chili, Spain, and Portugal were next described, and the discovery and mining of copper in the Lake Superior district. Subsequently the Australian deposits were opened up; Arizona and Butte entered into the producing areas; and recently progress has been made in Utah, Tennessee, Queensland, Tanganyika, Nevada, and Siberia. The chief features of modern copper-smelting practice in America—especially at Anaconda—were dealt with in great detail; and, finally, Professor Carpenter insisted on the need for exhaustive inquiry into the various aspects of the industry from the standpoint of Empire requirements, and of action to be taken on the basis of the results of the inquiry.

An interesting course on "High Temperature Processes and Products" was given by Mr. Charles R. Darling. In his first lecture he dealt with various methods of producing high temperatures, and described special fuel furnaces. The second lecture was devoted to high temperature processes, in illustration of which were shown the smelting of platinum and metals of high melting-point; welding and cutting by the oxy-acetylene flame and electric arc; thermit welding and metal spraying; while the production of steel and other metals by electric furnaces, and the fixation of atmospheric nitrogen, were also described. In the final lecture Mr. Darling discussed the principal high temperature products and their uses, particularly artificial graphite, carborundum, alundum, calcium carbide, siloxicon, carbon compounds, and aloxite.

It was somewhat of an innovation to select an economic subject for a set of Cantor Lectures, but the interest taken in Mr. Edgar Crammond's course justified the Council in their experiment. In three lectures Mr. Crammond discussed the economic condition of the United Kingdom before the war and after three years of war, and he also dealt with the real cost of the war and the problem of economic reconstruction. His arguments were illustrated by a great wealth of national statistics, on which he is a recognised authority.

The course on "Military Explosives of To-day," by Mr. J. Young, Chief Instructor in Science at the Royal Military Academy, Woolwich, attracted very good audiences. In the three lectures he dealt with propellants, high-explosive mixtures, and methods of detonation, illustrating each section of his subject with numerous experiments.

V.—Cobb Lectures.

A course of two lectures under the Cobb Trust was delivered by Professor Henry R. Procter, who gave four Cantor Lectures in 1899 on "The Manufacture of Leather." The subject of the present course was "Recent Developments in Leather Chemistry." The lecturer discussed the principal additions that have been made to the knowledge of the subject during the last eighteen years, and in conclusion mentioned a new process of chrome-tanning calculated to obviate the difficulties arising from the shortage of glucose and sugar. There had not yet been time to experiment to any great extent with the new method, but Professor Procter expressed his belief that it might be of very considerable use to the trade.

VI.—Special Lectures.

A course of three special lectures was given on a subject of great international interest at the present time—"The Freedom of the Sea." The first, by Mr. Gerard Fiennes, dealt with the question from the historical point of view; the second, by Sir Francis Taylor Piggott, from the point of view of international law; while the third, by Mr. John Leyland, analysed the modern German interpretation of the phrase, and showed how President Wilson's declaration is in conflict with the German claim.

VII.—Juvenile Lectures.

The Juvenile Lectures this session were delivered by Dr. P. Chalmers Mitchell, Secretary

of the Zoological Society of London. He selected as his subject "Animal Camouflage," and, aided by numerous lantern-slides, he gave an able exposition of the manner in which birds, beasts and reptiles contrive to make themselves inconspicuous amongst their natural surroundings.

VIII.—Albert Medal.

The Albert Medal of the Society for 1918 has been awarded by the Council, with the approval of the President, H.R.H. the Duke of Connaught and Strathearn, K.G., to Sir Richard Tetley Glazebrook, C.B., Sc.D., F.R.S., "for his services in the application of science to the industries of peace and war, by his work as Director of the National Physical Laboratory since 1899, and as Chairman of the Advisory Committee for Aeronautics."

Sir Richard Glazebrook has been the Director of the National Physical Laboratory since it was established. Under his superintendence and control it has developed from a tentative institution with a moderate income and a very small staff, into the greatest official scientific organisation of the country, with an annual expenditure of £100,000 and a staff of over 500. Instituted with the view of providing for the testing and standardising of instruments, appliances and materials used for industrial, scientific and other purposes, and for carrying out such researches as might be required in the efficient discharge of such duties, it soon discovered that its subsidiary object was really its essential duty, and it became the centre of organised practical and industrial research for the kingdom. As its usefulness became apparent, its value was rapidly appreciated by the heads of engineering and industrial enterprises, who in many cases contributed very large amounts of money to provide the costly buildings and apparatus frequently required for elaborate experimental researches on an industrial scale. As the result, much valuable special information has been provided for such very varied applications as engineering and naval construction, the various branches of metallurgy, the numerous uses of electricity, aeronautics, glass-making, the manufacture of optical and other scientific apparatus, the treatment of refractory materials, and numerous other branches of scientific industry. Many of the problems submitted were of the highest complexity, requiring for their solution wide scientific knowledge, costly apparatus, close and long-continued attention, patient and enduring labour. A special and important part of the laboratory work was the improvement, perfection and standardisation of an infinite variety of gauges and measuring instruments, while side by side with all this advanced scientific work it has regularly and efficiently carried on a large amount of its regular routine of testing and reporting on the very considerable number of instruments regularly sent to it for the purpose of its valued certificates.

The Laboratory has, from its foundation, been under the control of the Royal Society, exercised through a committee representing the Society and six great technical institutions. This committee, under its eminent Chairman, Lord Rayleigh, has always taken an active and efficient share in the administration of the Laboratory; but it is recognised on all hands that a large share of its success is due to the Director's personal efforts and influence, to his singularly wide general knowledge of physical science and its applications, and above all to the ability he has shown in the personal guidance of many of the difficult investigations which he has had to conduct or to control.

The Council of the Society therefore welcome this opportunity of adding their testimony, by the award of the Albert Medal, to the value of the services which Sir Richard Glazebrook has undoubtedly rendered to the advance of scientific industry by his work as Director of the National Physical Laboratory.

IX.—Medals for Papers.

The Council decided to award six medals for the papers read before the Society during the present session—four for papers read at the Ordinary Meetings, and one each for those read at the Indian and the Colonial Sections.

The following awards have been made:—

At the Ordinary Meetings:—

W. Lawrence Balls, Sc.D., "Examples of Applied Science in the Cotton Industry."

George Martineau, C.B., "Sugar from Several Points of View."

Professor J. Bretland Farmer, D.Sc., F.R.S., "The Rubber-Planting Industry."

Martin O. Forster, D.Sc., F.R.S., "Organic Chemistry in relation to Industry."

In the Indian Section:—

H. M. Surtees Tuckwell, M.I.Mech.E., "The Tata Iron and Steel Works."

In the Colonial Section:—

Sir Walter Egerton, K.C.M.G., LL.D., "British Guiana and the Problem of its Development."

For many years it has been the practice that no medals should be awarded to readers of papers who had previously received medals from the Society or were members of the Council. Acting on this rule the Council were precluded from considering the following papers:—

At the Ordinary Meetings:—

SIR DUGALD CLERK, K.B.E., F.R.S., "Discovery and Invention."

LORD LEVERHULME, "'Zero'" of Capital and Labour."

MONSIEUR PAUL LAMBOTTE, "Ypres and other Flemish Cities before and since the War."

MAJOR SIR ROBERT ARMSTRONG-JONES, M.D., R.A.M.C., "Mental Effects of the War and their Lessons in regard to Medical and Social Reconstruction."

In the Colonial Section:—

LIEUT.-COLONEL THE HON. SIR JOHN MCCALL, M.D., LL.D., "Land Settlement within the Empire."

The Council, however, desire to express their high appreciation of these papers.

X.—SWINEY PRIZE.

The next award of the Swiney prize will be in January, 1919, the seventy-fifth anniversary of the testator's death. Dr. Swiney died in 1844, and in his will he left the sum of £5,000 Consols to the Society of Arts, for the purpose of presenting a prize on every fifth anniversary of the testator's death, to the author of the best published work on Jurisprudence. The prize is a cup, value £100, and money to the same amount; the award is made jointly by the Royal Society of Arts and the College of Physicians.

In accordance with the arrangement with the College of Physicians, the award next year will be for Medical Jurisprudence.

Any person desiring to submit a work in competition, or to recommend any work for the consideration of the judges, should do so by letter addressed to the Secretary of the Society.

XI.—OWEN JONES PRIZES.

Under the Owen Jones Trust, six prizes were awarded each year from 1878 to 1915 to Students of Schools of Art on the results of the National Competition held annually under the direction of the Science and Art Department, and its successor, the Board of Education. In 1916 the Board of Education decided to suspend the "National Competition," and it was therefore no longer available as the means of awarding the prizes.

Last year, however, the Council determined to offer the prizes direct to the Schools of Art, and to appoint their own judges to make the awards. All the difficulties of arranging for the reception and examination of the competing designs were removed by the kind co-operation of the Director of the Victoria and Albert Museum, who consented to provide the necessary accommodation at the Museum, and to offer all facilities for their proper inspection and the adjudication of the prizes.

The competition was limited to Designs for Textiles. 120 designs or works were sent in from 22 Schools of Art by 73 students. According to the report of the judges * the work submitted showed a high average of excellence, and the designs were exhibited to the public from July 23rd to August 25th at the Museum.

In view of the success of last year's competition, the Council decided, with the courteous consent of the Director of the Victoria and Albert Museum, to follow similar lines in 1918, and notice was accordingly issued last November to the principal Schools of Art that the usual prizes would be offered for (1) Chintzes, and other Stamped, Printed, or Stencilled Textile Materials; (2) Wallpapers; and (3) Tiles.† The designs have to be delivered at the Museum between the 24th and 29th of the present month.

XII.—"TRUEMAN WOOD" LECTURE ENDOWMENT FUND.

On the resignation of the Secretaryship by Sir Henry Trueman Wood in 1917, the Council resolved to institute an annual "Trueman Wood" Lecture to commemorate the services rendered to the Society by Sir Henry during the thirty-eight years for which he had held office. The first lecture of the course was delivered by Sir Dugald Clerk, to which reference is made elsewhere.‡

In order to place the lecture on a secure and permanent basis, by providing a substantial yearly fee for the lecture, it was subsequently decided to invite past and present members of the Council to raise an endowment fund, and in response to a notice circulated among them, the sum of £654 18*s*. was subscribed.

XIII.—EXAMINATIONS.

The examinations were held this year, as in the three previous years, in two divisions, the

* See *Journal*, Vol. LXV. p. 603.

† For details of the competition, see *Journal*, November 30th, 1917, p. 23.

‡ See also page 502.

first from March 18th to 25th, and the second from May 6th to 15th. The entries for the March examinations were 10,944, and those for the May examinations 20,191, making a total of 31,135.

The highest number of entries ever reached was in 1914, when they totalled 37,974. In 1915, the first year of the war, they dropped to 32,113, and in 1916 there was a further drop to 25,968; in 1917, however, there was a slight increase to 26,185, and it is satisfactory to notice that this year the numbers have risen to 31,135, showing an advance of 4,950 over the total for 1917.

The entries this year included 443 from prisoners of war or interned men at Ruhleben, Groningen, Chateau d'Oex, and Mürren. Last year the corresponding figure was 279. From London centres 5,091 entries were received; while the remaining 25,196 came from 404 centres throughout the United Kingdom.

A number of entries for examination in Dutch were received from interned men at Groningen. As the Society does not ask these candidates to pay fees, and as there were no others, the Council did not feel justified in incurring the expense of holding an examination in this subject. The circumstances were laid before the Directors of the Standard Bank of South Africa, who generously contributed the sum of £20 to cover the cost of the examination, which has now been duly held.

The liberality of the Worshipful Company of Clothworkers has enabled the Council, as in past years, to offer the usual silver and bronze medals. These medals are very highly valued by the successful candidates, and there can be no doubt that they contribute not a little to maintain the high standard of the examinations.

The results of the First Division of the Examinations, held in March, have already been communicated to the candidates; and those of the May Division will be announced as soon as possible.

The usual detailed report of the examinations will be printed in the *Journal* in the autumn.

XIV.—Viva Voce Examinations in Modern Languages.

Up to the present date 13 examinations in French, German, Spanish, and English for Foreign Students have been held this year in London and Manchester.

At these examinations 234 candidates presented themselves, of whom 181 passed (78 with distinction) and 53 failed.

Other examinations have been arranged in Italian and Russian.

XV.—Conjoint Board of Scientific Societies.

As was stated in the Report of the Council for 1915-16, the Royal Society appointed a Conjoint Board of Scientific Societies, consisting of representatives of twenty-six societies, of whom the Royal Society of Arts was one.

In the two years which have since elapsed, the Board has been organised, the number of the constituent societies has been increased, an executive committee has been appointed, and numerous meetings both of this committee and of the Board itself have been held. Various committees for special purposes have been appointed and have carried through a considerable quantity of work.

The delegates appointed in the first instance to represent the Society were Sir Philip Magnus and Sir Henry Trueman Wood, who still continue in office.

A contribution of ten guineas has been made by the Council this year to the funds of the Board.

XVI.—Journal.

Up to the present year it has always been the custom to print the proceedings at the Wednesday meetings in the *Journal* of the following Friday, and there can be no doubt that the Society has gained great credit from this prompt publication. This session, however, owing to the drastic restrictions on the supply of paper, and its enormously increased cost, it has been found imperative to restrict each issue of the *Journal* to a "sheet" of sixteen pages. This, as a rule, only affords space for the reporting of one meeting, and as, with the Indian and Colonial Sections, there have been thirty-two meetings in twenty-seven weeks, there has necessarily been some delay in publishing the reports. The Council greatly regret this change, which is only temporary and entirely due to war conditions; but they believe that the Fellows generally will appreciate the difficulties under which the *Journal*, like all other periodical publications, is at present being produced, and will make allowances for its reduced size and for the delay in publishing the reports of meetings.

XVII.—New Council.

The Vice-Presidents retiring under the ordinary regulations are Sir George Ranken Askwith, Mr. Arthur James Balfour, Lord Faringdon, Lord Moulton, and Lord Newlands.

In their place the Council recommend Sir William Henry Davison, who has been a Treasurer since 1913; Sir Walter Egerton; Sir Robert Abbott Hadfield, who has been an Ordinary Member of Council since 1916; and Major F. G. Ogilvie and Sir Aston Webb, both of whom have held office on the Council in former years.

The four Ordinary Members of Council retiring are Mr. Alan S. Cole, Sir Robert Abbott Hadfield, Sir Robert William Perks, and Sir Henry Trueman Wood, who is nominated as a Treasurer. In their place the Council recommend Sir Charles Carrick Allom and Dr. M. O. Forster (neither of whom has yet served on the Council), Mr. John Slater, and Professor J. M. Thomson.

XVIII.—Obituary.

The Society sustained a very severe loss by the death of Sir John Wolfe Wolfe-Barry, which took place in January. He served almost continuously on the Council for twenty-four years, and he was Chairman in 1898–1900.

Earl Brassey had been a member of the Society since 1862, and he had served on the Council with few breaks from 1871 to 1882, and again from 1913 to 1915.

Mr. William Charles Knight Clowes was the senior partner of the firm of Messrs. William Clowes and Sons, Ltd., the Society's printers. He joined the Society in 1885, and was twice elected on the Council.

Mr. Samuel Charles Phillips was a recognised authority on the paper, board, and pulp industries, and he read three excellent papers before the Society.

Miss Ruth Morrish Day contributed the notes which appeared for about twelve years in the *Journal* under the title "Arts and Crafts." She was the daughter of the late Lewis Foreman Day, who, up to the time of his death in 1910, was a member of the Council.

Mr. Alfred Gordon Salamon gave a valuable course of Cantor Lectures in 1888 on "Yeast, its Morphology and Culture," and he also received a silver medal for a paper on "The Purity of Beer."

Among other notable Fellows of the Society who have died during the year may be mentioned Mr. Charles Hawkesley, the Hon. Rowland Gibson Hazard, the Hon. Sir Sundra Lal, Sir William Heerlein Lindley, Vice-Admiral William Usborne Moore, Mr. Alfred de Rothschild, Sir Swire Smith, Mr. Thomas Tyrer, and the Earl of Rosse.

XIX.—Finance.

Two changes have been made in the Financial Statement which, in accordance with the usual practice, was published in the *Journal* of June 21st — the first in the dates of the financial year, the second in the form of the Statement.

Hitherto, the Society's financial year has run from June 1st to May 31st, these dates having no doubt been chosen so that the accounts might be brought as nearly as possible up to the date of the Annual Meeting, which is fixed by By-law 39 for the last Wednesday in June. The question of the receipts and expenditure in connection with the examinations has, however, tended more and more, as the amounts involved have increased, to make these dates inconvenient. The receipts came in before May 31st, while the bulk of the expenditure was made after that date, with the result that it was impossible to show the receipts against the expenditure for the same set of examinations, and this militated against the reliability of the Financial Statement in showing the precise financial position of the Society at a given date.

The second change is in the form of the accounts. Instead of the former "Statement of Receipts and Payments" the auditors have prepared an "Income and Expenditure Account" for the year ending December 31st, 1917, and a "Balance-sheet" as on that date.

The Income and Expenditure Account shows that for the year 1917 there was an excess of expenditure over income of £346. This sum is mainly due to the enormously increased costs of printing and paper. On the other hand, as already mentioned,* there has been a very marked rise in the number of new Fellows—373 for the Session, 1917–18, as compared with 164 for 1916–17—while the amount received in Life Compositions this session, £849, is the largest received under this head since 1862.

The Chairman (Mr. Alan A. Campbell Swinton, F.R.S.) moved the adoption of the report. All would agree, he said, that it was very complete and comprehensive. It was a source of great satisfaction that so many new Fellows had joined the Society during the past year, and that the numbers were now increasing instead of diminishing, as was the case at the beginning of the war. It was to be remembered that the Society derived its revenues principally from the subscriptions of the Fellows, and it was

* See page 502.

therefore most important that the numbers should be kept up. There had also been a large increase in the examination entries, which was very satisfactory. They would remember that in consequence of the expenses of the examinations exceeding the receipts from entrance fees, it had recently been necessary to increase the amount of the fees charged to candidates. It was therefore very gratifying to find that, in spite of this small extra charge, the numbers had increased by nearly 5,000 this year. They had had a most interesting series of papers and lectures this session, especially those dealing with the application of science to particular branches of industry. The Indian Section had been as active as usual, and had now entered upon its Jubilee year. The award of the Albert Medal to Sir Richard Glazebrook in recognition of the great work he had accomplished at the National Physical Laboratory had met with general approbation. The question of the finances of the Society had given the Council a certain amount of anxiety, owing to the greatly increased cost of printing and paper, more particularly in connection with the *Journal*. The Council felt, however, that it was the *Journal* which, to a large extent, kept the Society, with its widely-scattered Fellows, together. It was a valuable educational publication, and they considered its continuance most essential, even if the Society did incur a small loss by continuing its issue.

Sir Henry Trueman Wood said it gave him very great pleasure to second the adoption of the report. It would have been a great source of regret to him if, at the end of the first year of his retirement, there had been any falling-off in the activities of the Society. It was therefore with sincere satisfaction he saw how well the work of the Society had been carried on during a very difficult year. Of course, everyone realised that the diminution in the number of Fellows was mainly caused by the war, and it was extremely satisfactory, and reflected great credit upon those responsible for this branch of the Society's work, that there was such a distinct and considerable increase in the number of new Fellows elected this year, for after all that was the truest test of a Society's progress and stability. He looked upon the examinations as a very important part of the Society's work, and the increase in numbers was also quite satisfactory, as it showed that under normal conditions they would again reach the pre-war figures. The Society's finances were in a perfectly sound and satisfactory condition, and in conclusion he wished to express his sincere thanks to the past and present members of the Council for the very liberal and handsome manner in which they had raised the endowment fund to commemorate his Secretaryship of the Society.

Mr. Edward T. Scammell thought attention should be drawn to the good work the Society had done in holding examinations for the interned prisoners at Ruhleben, Groningen, etc. He also remarked on the comparatively small number of Fellows the Society had in Canada and Australasia, and suggested that the Colonial Section might take advantage of the presence in this country of distinguished overseas statesmen to interest them in the economic value of the Society's work, with a view to an increase in the number of Colonial Fellows. Important papers dealing with the economic development of the Empire had been read before the Society, and he thought greater attention might be drawn to the work which the Section had been carrying on for the benefit of the Colonies for so many years.

The Chairman said Mr. Scammell's suggestion would, he was sure, receive the careful consideration of the Council.

The adoption of the report was then agreed to.

The ballot having remained open for half an hour and the scrutineers having reported, the Chairman declared that the following had been elected to fill the several offices. [The names in *italics* are those of Fellows who have not, during the past year, filled the office to which they have been elected.]

President.

H.R.H. The Duke of Connaught and Strathearn, K.G.

Vice-Presidents.

Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.

Lord Blyth.

Sir William Henry Davison, K.B.E., D.L.

Sir (Frederick) William Duke, G.C.I.E., K.C.S.I.

Sir Walter Egerton, K.C.M.G., LL.D.

Peter MacIntyre Evans, M.A.

Sir Robert Abbott Hadfield, D.Sc., D.Met., F.R.S.

Field-Marshal Sir Douglas Haig, K.T., G.C.B., G.C.V.O., K.C.I.E.

Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.

Lord Islington, P.C., G.C.M.G., D.S.O.

Lord Leverhulme.

Major Percy A. MacMahon, R.A., LL.D., Sc.D., F.R.S.

Sir Philip Magnus, Bt., M.P.

Viscount Northcliffe.

Major-General Sir Desmond D. T. O'Callaghan, R.A., K.C.V.O.

Major Francis Grant Ogilvie, C.B., LL.D.

Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.

Hon. Richard Clere Parsons, M.A.

Sir Boverton Redwood, Bt., D.Sc., F.R.S.E.

Lord Sanderson, G.C.B., K.C.M.G.

Alan A. Campbell Swinton, F.R.S.

Sir Aston Webb, K.C.V.O., C.B., R.A.

ORDINARY MEMBERS OF COUNCIL.

Sir Charles Carrick Allom.

Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.

Edward Dent, M.A.

Martin Onslow Forster, D.Sc., F.R.S.

Major Edward Humphrey Manisty Leggett, R.E., D.S.O.

William Henry Maw, LL.D., M.Inst.C.E.

Sir Francis Taylor Piggott, M.A., LL.M.

John Slater, F.R.I.B.A.

James Swinburne, F.R.S.

Professor John Millar Thomson, LL.D., F.R.S.

John Augustus Voelcker, M.A., Ph.D., F.I.C.

Sir Frank Warner, K.B.E.

TREASURERS.

Carmichael Thomas.

Sir Henry Trueman Wood, M.A.

SECRETARY.

George Kenneth Menzies, M.A.

On the motion of the CHAIRMAN, a vote of thanks to the scrutineers was carried unanimously.

THE CHAIRMAN proposed a cordial vote of thanks to Mr. G. K. Menzies (the Secretary), Mr. S. Digby (the Secretary of the Indian and Colonial Sections), Mr. George Davenport (the Chief Clerk), Mr. J. H. Buchanan (the Accountant), and to the other officers of the Society for their services. He thought the Fellows would agree that this had been a very satisfactory year so far as the Society was concerned, and that this was really due in a great measure to the officers of the Society. Although some of them felt when Sir Henry Wood retired that they would never be so well served again, he felt sure they would agree that the Society had got the next best Secretary it was possible to have.

SIR BOVERTON REDWOOD, Bt., D.Sc., F.R.S.E., had very great pleasure in seconding the vote of thanks. Since the commencement of the war it had been a very difficult matter to discharge duties like those which fell to such a Society as theirs, and the record of work done left nothing to be desired. He cordially endorsed the remarks as to the high standard of excellence of the papers this session, which he said was in no small measure due to the efforts of the Secretary, who, it might truthfully be said, was a worthy successor of Sir Henry Trueman Wood. The other members of the staff were also deserving of their warmest thanks for their loyal services.

THE SECRETARY (Mr. G. K. Menzies) returned thanks for this expression of confidence in himself and in the other officers of the Society. As this was the first opportunity he had had since Sir Henry Wood's retirement he wished to say how much he owed Sir Henry for his training, and with what pleasure he had served under him for the past nine years. The Indian Section had had a very successful session, and the results had certainly justified the amount of labour Mr. Digby had bestowed upon it. The examination staff deserved the credit given to them, and the other members of the staff had earned his gratitude also for the generous way in which they had helped him to carry on the work.

A hearty vote of thanks was accorded to the Chairman (Mr. Alan A. Campbell Swinton) for his services.

The meeting then adjourned.

ENGINEERING NOTES.

Marine-power Progress.—Mr. W. B. Esson, in his paper before the Society of Engineers, stated that it was not until 1862 that the cylindrical boiler met with any degree of success, and he commented on the somewhat remarkable fact that this type now remains in almost universal use, and has been altered only in detail since that early period. The advantage of the water-tube boiler, which is now being manufactured by many firms, is that it can be adapted with more ease to the particular requirement it has to meet than any other boiler of the shell type In marine engines the introduction of the triple-expansion type, working at about 150 lb. pressure, enabled great economies in steam consumption to be effected. In terms of fuel consumption, the modern triple-expansion engine requires from 1·46 lb. to 2 lb. of coal per i.h.p. per hour, and the compound engine from 2 32 lb. to 2 39 lb. The steam turbine for any power over 1,200 h.p. shows an even lower steam consumption. To summarise the results of a large number of tests, it may be said that with 160 lb. pressure and 27 inch vacuum a 3,000 kw. turbo-alternator set will take only 16 lb. of steam per kw. hour. In the 40,000 h.p. turbine recently constructed for the Chicago power-house the steam consumption is guaranteed not to exceed 11·25 lb. per kw. hour with steam at 200 lb. pressure and a superheat of 200° F. As regards geared turbines employed in marine service, the London and South-Western Railway steamers "Hantonia" and "Normannia" show a saving of 40 per cent. over ordinary turbine steamers on the same service.

Tanks in France.—These have been engaged recently in the Aisne sector of operations on the Western front, and have done good service. The French "Tank," like ours, works on caterpillar wheels, but differs in being smaller and having a somewhat greater manœuvring power than our early models. It carries a field gun in addition to several machine guns, and experience has led not only to improvements of structure and armament,

but to a clearer idea of the most advantageous method of using such war-cars.

Irrigation in Mesopotamia.—A correspondent in the *Times* and other papers recently, relates, among other news, that this year, owing to the success of the Euphrates irrigation scheme, the supplies from the Euphrates side will be enormously increased, and the transport of the country will be hard put to it to bring in the grain. During the summer we have been at work on the scheme connected with the Hindieh barrage, designed by Sir William Willcocks and constructed by Sir John Jackson's firm. It was finished before the war, but the Turk neglected to profit by it. The canalisation work connected with it was left incomplete, and the area to be cultivated was never brought under irrigation. The Euphrates divides at Hindieh into two branches—the Shatt-el-Hilleh to the east, and the Shatt-el-Hindieh to the west—and the two channels of the river meet again a few miles above Samawa. Until the nineteenth century the Hilleh branch carried the main canal, but during the last century the bulk of the river has been diverted to the Shatt-el-Hendieh, which was the main channel more than a thousand years ago. The function of the barrage was to provide water for the Hilleh branch, which was silting up, while the bed of the Hindieh branch was scouring out and its water was being wasted. This year nearly a hundred canals on the Hilleh branch, which had fallen into disuse, have been dug out, 300,000 acres have been brought under cultivation, and there is promise of the greatest harvest in the memory of man—possibly the greatest since the days of Nebuchadnezzar.

Tungsten Deposits.—Some of the important deposits of wolframite, a tungsten ore, occur in Asia, and have become of extreme importance since we declared war, as high-speed steel depends for its production on tungsten. The better qualities of high-speed steel contain as much as 18 to 20 per cent. of pure tungsten metal, produced in the form of a fine, dull black powder from the ore. There are several varieties of it, known as (1) wolframite, (2) scheelite, (3) hubnerite, (4) ferberite, all differing in their chemical composition. Wolframite consists of tungsten, iron, manganese, and oxygen, and is frequently found, as in Burma, associated with tin ores. It is a black, or greyish black, extremely heavy mineral, with a specific gravity as high as 7·5. It fuses easily, and is slightly magnetic, an extremely useful attribute, as it enables the wolframite to be separated from the tin ore, when crushed to a powder, by means of magnetic operators. Scheelite consists of tungsten, calcium, and oxygen; in colour it is a great contrast to wolframite, as it is white, yellow, brown, or approximately red; it is not as heavy as wolframite, as the specific gravity is only 6·1, and is practically infusible by any ordinary methods: it can be decomposed by hydrochloric acid; it does not effervesce in acids, and it does not turn a silver coin black, which has been heated and moistened. Ferberite, which consists of tungsten, iron, and oxygen, is the prevailing form of ore found in the United States. Hubnerite consists of tungsten, manganese, and oxygen: it is a brown, brownish red, or black ore; its specific gravity is a very high one, as much as 7·2; it is not readily fused, and can also be decomposed by hydrochloric acid. Another form is known as ferro-tungsten, an alloy of tungsten and iron obtained by removing the oxygen contained in the oxides of the ore. The tungsten ores, according to the *Indian and Eastern Engineer*, are extensively distributed in many Asiatic countries—India, Burma, the Malay States, Japan, Korea, Siam, Indo-China, and the Dutch East Indies.

Tar Oil for Diesel Engines.—The Controller of Munitions Mineral Oil Production has recently appointed a committee to assist him in connection with the subject of fuel oil supplies, and the use of tar oil as fuel in Diesel engines, and of methods to adopt Diesel engines for the use of tar oil. This committee is to be styled The Heavy Oil Engine Fuel Committee. The office is at 19, Cadogan Gardens, S.W. 3. In connection with the above, the *Auto* announces the discovery of a new motor fuel, of which a trial has been made with most favourable results, a motor-car carrying six persons climbing the steepest hills in Paris without the least trouble. The *Auto* explains that this new fuel is produced by the distillation of heavy oils obtained from coal. All the by-products will be available for the preparation of explosives. The new fuel, the newspaper adds, does not foul the cylinders, nor does it leave a residue of carbon.

OBITUARY.

ISAAC SHONE.—Mr. Isaac Shone, M.I.Mech.E., died at his residence in Putney on June 19th, aged eighty-two. He was the inventor of the Shone pneumatic sewage ejector, an early description of which is to be found in a paper on "Sewage Disposal at Wrexham," read before the Society's Annual Sanitary Conference, in 1879, by Lieut.-Colonel Alfred S. Jones, V.C., Assoc.M.Inst.C.E. At that time Mr. Shone lived at Wrexham and was Mayor of the borough. As mentioned by Mr. J. Forrest Brunton, in the paper recently read by him before the Indian Section, the Shone system was installed between 1892 and 1895 at Karachi and has since been extended there with beneficial results, being specially suited to towns so flat that drainage by gravitation is impracticable. The city of Chicago adopted the plan for its drainage works some years ago. Mr. Shone was a Fellow of the Society, having been elected as long ago as 1879.

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

FRIDAY, JULY 5, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 15th, 1918; Professor William Bateson, M.A., F.R.S., Director of the John Innes Horticultural Institution, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Brain, Henry Richard, London.
Johnson, Hubert, Hull.
Khoo Sian Ewe, Penang, Straits Settlement.
Major, John Lewis, London.
Mhatre, Succaram Vassuded, Bombay.
Parsons, Charles Frederick, London.
Paul, William Hewitt, Birkenhead.
Poulter, Captain Herbert William, Baghdad.
Saklatwalla, B.D., B.Sc., Dr.Ing., Pennsylvania, U.S.A.
Smith, J. Hatchar, F.R.I.B.A., London.
Symington, William, Bickley, Kent.
Wolseley, William Augustus, London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Cleminson, H. M., London.
Dutton, Reginald John Garfield, Skegness.
Howell, Alderman Thomas H., Newport, Monmouth.
Librarian, National Library of Ireland (Department of Agriculture and Technical Instruction), Dublin.
Martineau, William, Wallingford.
Oury, Libert, London.
Taylor, W. Howson, West Smethwick.

The paper read was—

TIMBER INDUSTRY.

By Percy Groom, M.A., D.Sc., F.L.S.,
Professor of Technology of Woods and Fibres, Imperial College of Science and Technology.

This paper will mainly deal with the extent to which technical science can aid, or has aided, in promoting the timber industry in this country and the utilisation of the timber resources of the British Empire. Although it is obvious that practical details in trade will constitute limiting factors of the extent to which organised application of technical knowledge can be of immediate commercial and Imperial service, little consideration will be given to obvious practical questions such as the impending revision of the relations between employer and employee; the wisdom of improved organisation of the timber trade along lines that are in the interests of the trade, the nation, and the Empire; and the effect of tariff reform.

The special qualities of timber that render it all-important in daily life may perhaps be best understood if we consider the demands made on wood in the living tree, which is exposed to various vicissitudes during its prolonged existence. The wood at the base of a tree-trunk has to withstand tons of pressure per square inch, while the trunk has to resist the bending action associated with its columnar form and the shearing tendency of its boughs. The trunk and branches have to resist shock caused by gusts of winds acting on a large head of foliage. Yet the young wood of the twigs or outer parts of the trunk must possess a certain degree of extensibility and toughness, as opposed to brittleness, so that they can endure change of shape under shock. Since one essential function of the wood is to conduct rapidly water to the leaves, wood must necessarily contain water-channels, and therefore be an excavated not a solid material. And since the water conveyed contains substances in solution, wood is capable of impregnation by watery solutions of dyes and preservatives. Remembering the great heights attained by certain tree-trunks, and the immense load of branches, it is necessary that wood in the tree be relatively light in weight when compared with its strength and stiffness. Finally, it is evident that wood in the tree must possess a certain degree of durability.

These various qualities essential to wood, in order to make possible the existence of a tree, render timber a material having unique properties as regards strength, elasticity, extensibility, and above all confer upon it a general superiority to metals as regards comparative weight and strength. The feeble powers possessed by wood of conducting heat, the relative ease with

which it is worked, and the great variety of timbers available, enhance its value and add range to the variety of uses to which it can be put as a structural material. Moreover, in certain situations, or when appropriately treated, wood is far more durable than iron; and can be subjected to processes by which it successfully withstands temperatures at which iron flows away as a molten liquid. Consequently as a *structural* material wood subserves purposes too familiar and numerous for enumeration.

When disintegrated it yields *fibres* that provide paper and cordage; while as a *chemical* complex wood is a fuel, and is the source of substances as diverse as charcoal, alcohols, acetone, formalin, artificial silk, turpentine, dyes, scents, and drugs.

New uses for wood are constantly being discovered and old uses being increased, so that with the advance of civilisation the consumption of timber per head of population steadily rises, despite its replacement for certain purposes by other materials such as iron and ferro-concrete. Hence in this country and the British Empire generally we know that there will be an ever-widening demand for timber.

The amount of wood used by this country may be estimated by a consideration of the imports in 1913.

In 1913 the values of the imports of timber into the United Kingdom were :—

	£
Softwood (conifer) logs, sawn, planed, etc.	22,800,000
,, ,, pit-timber	4,400,000
,, ,, wood-pulp	5,425,000
Total	£32,625,000
Hardwood, oak-logs	1,700,000
,, wood manufactures	4,600,000
,, teak, mahogany, furniture, etc.	3,800,000
	10,100,000
Softwoods and hardwoods. Total	£42,725,000

In addition, there was consumed a large amount of wood grown in the United Kingdom.

The largest item is represented by *softwoods*, which grow in the north-temperate regions, and are actually exported thence to tropical and southern countries. In the British Empire there is therefore only one great source of supply, namely, Canada. The supplies of softwoods are steadily decreasing in amount and receding in accessibility. The depletion of supply is particularly marked and serious in reference to constructional softwood of large dimensions and good quality. At present Douglas Fir (British Columbian pine), some pitch-pine in the United States, and some Scots pine in the recesses of Russia, represent such large timber. When these stocks have vanished they will probably never be replaced, because in modern forestry operations conifers in artificial forests are felled at the age of seventy to eighty years, as they then yield the optimum return.

It is therefore evident that the price of softwoods will continue to rise, and the more so with the increasing demands made by the growing southern nations in Australia, South Africa, and elsewhere.

What steps are to be taken to alleviate the threatened situation? In answer, four possibilities suggest themselves :—

1. Increased production of softwoods in this country, and the British Empire generally, by *afforestation.*
2. Partial substitution of hardwoods grown in British Colonies and Dominions for softwoods imported from foreign countries.
3. Maximum avoidance of loss and waste.
4. Further economy in the usage of timber.

Dealing first with the last possibility, the question arises: Is this country extravagant in its consumption of wood? The answer must be in the negative, since the subjoined table proves that the annual consumption per head of population is less than that of any other Great Power, with the solitary and small exception of Italy.

APPROXIMATE ANNUAL CONSUMPTION OF WOOD IN CUBIC FEET PER HEAD OF POPULATION.

United States	260
Canada	192
Russia	63
Austria-Hungary	57
Germany	36·6
France	24·6
United Kingdom	14
Italy	13

Although the consumption of wood in this country is not extravagant, I shall show later in this paper that not inconsiderable economy is possible.

The question of *afforestation* in the United Kingdom has been repeatedly considered by Governments. The scheme appealed rather to statesmen than to politicians, and as a commercial proposition promised only a modest return at a distant date. Recent experience has, however, introduced a broader outlook, which recognises the direct and indirect effects of forestry upon agriculture, rural re-population,

and the defence of the country, so that sanction has been given to a scheme in Great Britain. Years ago I endeavoured to interest the War Office in a scheme of combining an increase in the Army with the initiation of afforestation that should be carried out by a staff mainly recruited from men who had served in the regular Army or were auxiliaries in the Army. It is to be hoped that some such plan, taking cognisance of the existence of the Royal Air Force, will be considered for adoption throughout the British Empire.

The success of any measures, including afforestation, designed to improve conditions in this country as regards the timber industry, will depend finally upon the extent to which the pertinent scientific and technical knowledge is acquired and applied. The remainder of this paper will therefore be devoted to a survey of the fundamental facts and principles that have been learnt through research, and to some mention of problems calling for solution.

The chief, but not exclusive, problem of afforestation in this country is the successful production of coniferous timbers or softwoods. Great Britain with its temperate island climate is well suited for the growth of conifers, and taking into consideration its ranges of temperature, altitude, and soil, I am of opinion that the British Isles are better suited than any other country in Europe for the cultivation of a wide range of conifers. The main question, however, is not the successful growth of the tree but the successful production of timber of proper quality; the former does not necessarily involve the latter. Yet we do know that good coniferous timber can be grown in this country. Years ago, by means of mechanical tests at the Imperial College, it was discovered that timber of Scots pine grown even in the south of England is suitable for paving the streets; while last year mechanical tests proved that not only in the south of England, but also in the highlands of Scotland the Scots pine can yield slow-grown timber that is equal to the highest demands ever made on wood, namely, use in vital parts of aeroplanes.

Now not only do the timbers of different kinds of trees differ in their qualities, but the timber of one and the same species of tree varies according to the conditions under which it is grown. Therefore, if timber of the best quality is to be produced, it is necessary to be able quantitatively to estimate the mechanical values of different samples, and to analyse the conditions under which these have grown, so that in forestry operations the correct treatment may be adopted in connection with each species of tree. Some of the valuable results obtained in this connection by the researches of botanists, foresters, and mechanical engineers, may now be considered.

Timber is not strictly a material, but is an elaborately designed structure, consisting of solid wood-substance excavated so as to form a framework. The elementary structural units of wood are hollow: their solid walls and sometimes their cavities contain water; the portions of their cavities unoccupied by water are mainly filled with air. When a piece of wood is completely dried its weight may be regarded as wholly due to the solid framework of wood-substance (though this is not absolutely correct). Inasmuch as the specific gravity of the wood-substance of all kinds of timbers investigated is approximately the same (viz. about 1·55 or 1·56), it follows that the so-called specific gravity, or the weight per cubic foot, of absolutely dry timber is a sufficiently correct indication of the amount of wood-substance in it. A "heavy" timber has much wood-substance, a light timber has only little wood-substance. Hence it follows that the strength, stiffness, hardness, and heating power of timbers tend to be proportional to their respective specific gravities, so long as they contain the same percentages of water. This tendency is at a maximum when different samples of one and the same kind of timber are in question.

In the case of the most important of all coniferous timbers, the Scots pine, the specific gravity and compressive strength of the heaviest wood are more than three times those of the lightest wood. If comparison be made of the timber of this tree grown on similar soils and with similar treatment, but in different climates, changes in structure of the wood are revealed to the naked eye. As the climate becomes colder growth is slower and the annual growth-rings of the wood are narrower, but this diminution of the thickness of the rings takes place more at the expense of the soft light spring-wood than of the heavier harder red summer- (autumn-) wood. Hence the narrow-ringed wood is heavier and stronger. When, however, the climate becomes too severe—as in regions nearing the Arctic zone—the attenuation of the growth-rings continues but the wood is lighter in weight and weaker; such is the red deal exported from the White Sea. A knowledge of these facts rendered possible during the present war the correct anticipation of the occurrence in the

highlands of Scotland of slow-grown, light Scots pine, eminently suited for use in aeroplanes. Variations in the soil and in the light to which Scots pine is exposed cause corresponding changes in the structure and properties of the wood. One example of the comparative effects of knowledge and ignorance in these matters may be cited in reference to the present war. Germany having made thousands of mechanical tests and observations on the structure of Scots pine growing in various forests of that country, was able instantly to secure rich supplies of this wood of exactly the quality required for aeroplanes. In this country, until the present war began, we did not know the mechanical values of any kind of timber whatsoever growing in the United Kingdom, still less did we know the values for the different varieties of one timber, nor where these varieties were to be found: we were compelled to find and then test the woods that might be suitable.

Results similar to those obtained in regard to Scots pine hold good for Norway spruce (*Picea excelsa*), as is proved by the subjoined values obtained by Professor Janka on this wood grown in Austria:—

Width of annual ring (in millimetres).	Specific gravity($\times$100).		Compression parallel to the grain (crushing stress in kilograms per square centimetre).	
	Seasoned.	Absolutely Dry.	Seasoned.	Absolutely Dry.
·5—1	44·9	41·7	397	743
1—1·5	44·3	41·3	395	729
1 5—2	43·1	40·2	386	708
2—2·5	41·9	38·9	364	666
2·5—3	41·3	38·4	353	647
3—3·5	39·9	37	339	622
3·5—4	40·2	37·2	342	619
4—4·5	39·1	36	314	581
4·5—5	40·2	36·8	308	554
Above 5.	38·1	34·9	306	510

By way of contrast to the softwoods discussed, hardwoods of the type of the oak and ash may be considered. In these, as the growth is more rapid, the increased width of the annual rings is often mainly caused by disproportionate additions to the hard, heavy, fibrous summer-wood produced outside the soft, weak, porous spring-wood. In the case of the oak there is probably a limit to this tendency, as towards the south of Europe oak timber, though wide-ringed, is slightly softer than that grown in our own climate. The weakness of narrow-ringed porous ash-timber is familiar to all practical men, especially in connection with those trees that have grown slowly under the influence of excessive shade.

In timbers of this type there is a decline in weight and strength when the annual rings are of the same thickness, but there is a wider zone of porous wood (due to a larger number of series of pores). Monsieur Thil found, for instance, in oak, where each annual ring was half a centimetre in thickness, that the tensile strengths of three samples, showing respectively 1, 2 to 3, and 3 to 4 series of pores in the spring zone, were 17·1, 13·6, and 12·7 kilograms per square millimetre.

The tendency for opposite effects to be induced in pine and ash timbers by widening or narrowing of the annual rings explains one practical matter in connection with parts of aeroplanes in which the wood is used in the form of thin laminae or is spindled out; the pine must not be wide-ringed, whereas the ash must not be narrow-ringed. Another practical lesson in this connection may at once be learnt by anyone observing the variety of qualities or grades of blocks of Scots pine paving streets in London. He will then note that in certain parts of London the use of inappropriate grades of this wood causes great economic loss and unnecessary public inconvenience.

Mechanical tests on timbers, apart from providing one of the bases for sound forestry, are of value in yielding the necessary information as to the minimum dimensions required by constructional wood used for specific purposes. They thus render possible the utmost economy and the substitution of one wood for another.

Afforestation in Great Britain can yield considerable supplies of softwoods only many years hence; consequently the provision of substitutes in the form of hardwoods grown specially in British tropical Colonies would be of great economic importance if practicable. There are, however, both technical and commercial difficulties in the way.

The extensive use of softwoods as structural material is due to several sets of factors. First, coniferous trees grow in the north-temperate regions, forming forests that are pure or contain large numbers of the same species of tree. Softwoods are thus accessible and can be obtained cheaply: this is especially true of Baltic softwoods. These coniferous timbers are usually easy and cheap to work, often display high strength-values when compared with their weights ("specific gravities"), tend to shrink less than hardwoods, and generally are more easily and rapidly seasoned than are the latter,

while as sources of fibre and paper they yield a very high percentage of fibre.

On the other hand the hardwoods abounding in the vast forests of the British tropical and southern Dominions and Colonies are generally more distant, for even the West African Colonies are farther away than the Baltic. Moreover, the hardwood trees in them grow together in mingled confusion, hundreds of different species growing side by side. Consequently definite kinds of hardwoods are less accessible than are softwoods.

Yet many of the hardwoods have certain advantages on their side. In moist tropical countries their growth is generally much more rapid than is that of the northern conifers, and there is no present demand for certain of them, indeed in some cases they represent obstructions that have to be removed and destroyed. Considering the amount of loss involved in the artificial destruction of tropical trees, the utilisation of such waste wood forms a problem of first-class economic import. Investigations will show that numbers of these inferior neglected woods can be utilised either as substitutes for softwoods of the better quality, or as fibre-yielding material to be used in the manufacture of paper, or chemically to yield alcohol, and so forth.

As regards hardwoods of better quality, and often greater weight, some may be employed as substitutes for hardwoods—such as oak, teak, and mahogany—that are partly imported from non-British countries, or may be more vigorously exploited in foreign lands. But to accomplish these aims full information as to the mechanical and working properties of such woods is required. We have very little detailed information as to the mechanical and other properties of such timbers. Yet investigations conducted during the present war have demonstrated the suitability for use in aeroplanes of certain mahoganies and other hardwoods from British West Africa, Papua, Queensland, British East Africa, and India, and of certain softwoods from New Zealand and British East Africa.

These considerations lead once more to the study of the structure of timbers, whose significance in affording guidance to the qualities and uses of woods has already been indicated. Research into the structure of timbers is also necessary as a means of rendering possible the critical *identification*. Such identification is needed in order that a person shall secure exactly the kind of wood that he requires. At present the commercial nomenclature of timbers is in confusion. For instance, in various parts of Australia the same names are applied to different timbers, and different names to the same timber: such practice militates against the sale of these woods in this country, for it may be said that every kind of wood has certain uses for which it is fitted better than any other. To select another example; a number of kinds of wood varying widely in colour, structure and properties, are sold in this country under the name of West African mahogany. Apart from the disappointment experienced frequently by purchasers, and the consequent tendency for West African mahogany to be discredited, this particular case is not devoid of national significance. I believe that the most motley array of such so-called mahoganies before the war came from the German Colony, Cameroon, which did not export anything like the same quantities as did the British and French Colonies. The natural result would be that the wrong attachment of the name of mahogany to the German spurious mahoganies would inflate their price, while lowering the price of British and French genuine woods. In importing the latter Germany would profit doubly.

So far no reference has been made to the great part played by water present in wood. By exhaustive tests it has been proved that the strength, stiffness, and hardness (when measured by indentation), of one and the same piece of wood vary inversely as the amount of water contained in the wood-substance itself. The table already given shows that in the case of spruce the absolutely dry wood has far greater resistance to crushing than has the merely seasoned wood. The pliability and ductility of wood, on the contrary, increases with rise in the water-contents, and greatly so if this be accompanied by rise in temperature. Wet-steamed wood can, therefore, be compressed to form railroad keys or bent to yield furniture; whereas very dry wood permits of only slight deformation, and in this sense is brittle.

So far two reasons exist in favour of drying wood before use—decrease of weight, and improvement of mechanical qualities; and these are accompanied by a third, which is associated with the changes of shape and dimensions of wood as it absorbs or emits water.

When once all the water has been removed from the cavities of the wood (and even before this when drying is relatively rapid) wood shrinks steadily as it continues to dry. Shrinkage is far the least along the grain; while across the

grain it tends to be much greater circumferentially than radially. Hence, during drying, a piece of timber would undergo considerable distortion were it not that wood possesses ductility. As a matter of fact such distortion in the form of warping or twisting often does take place in bastard-cut boards or planks when the process of drying is carried on too rapidly, and the warping may be accompanied or replaced by splitting in a radial plane.

This differential shrinkage along and across the grain partially accounts for the practice of cutting up highly figured wood and knotty burr-wood into thin and relatively small veneers. Somewhat akin to this veneering process is that of the manufacture of *ply-woods*. In three-ply wood, for instance, as the outer sheets or plies have their grain in a direction at right angles to that of the middle sheet or ply, the outer and middle plies tend to check each other's tendency to shrink or increase in surface. Moreover, since wood is much stronger along than across the grain the three-ply possesses a combination of transverse and longitudinal strength impossible in a single piece of the thickness equal to that of the three-ply. In ply-woods the plies glued together may number from three up to seventeen or perhaps more, and may be composed of a single kind or several kinds of wood. The manufacture and use of ply-wood is only in its infancy, and is bound to increase greatly, as, apart from the merits already mentioned, it renders possible the structural utilisation of cheap and relatively weak woods, which, if desired, can easily be impregnated with substances that render them decorative, fire-proof, or resistant to decay. While ply-wood and the woods yielding them are practically exclusively imported from foreign countries, there certainly exist in the various countries of the British Empire timbers that are not being utilised at all or to best advantage but yet are eminently fitted for use in ply form. But our knowledge on the technology of ply-wood requires amplification by research on a whole series of problems concerning the woods and adhesives suitable.

To return to the question of the relations subsisting between wood and water, it is known that a piece of wood continues to dry until at least its surface is in moisture-equilibrium with the water-vapour of the surrounding air. Thereafter it will absorb or exhale water according as the air becomes drier or moister, so that it is always shrinking or swelling. By limiting these interchanges of moisture, coatings of varnish, paint, and the like reduce such movements; but up to the present no one has solved the profoundly important problem of rendering wood absolutely impervious to moisture.

The preceding remarks provide sufficient justification for the *seasoning of timber*. Such seasoning was originally, and is still usually, accomplished by storing the felled wood in the open air, with or without a roof to screen it from rain and direct sunlight. This so-called "natural seasoning," being dependent upon climate, is prolonged and irregular, sometimes in abeyance and at other times too rapid. The prolonged storage not only ties up capital, but also involves loss of wood through decay or boring insects; while its occasionally excessive rapidity introduces loss due to case-hardening, warping, or splitting.

The early discovery that seasoning is the consequence of a process of desiccation led to the drying of wood by artificial heat. Primitive methods caused unduly rapid superficial desiccation and consequent development of defects (splits, brittleness and so forth). Improvements, including the regulation of temperature, moisture of the air, and air-currents in a drying chamber or kiln, have rendered possible the balanced drying of the inner and outer parts of the timber, and have culminated in modern methods by which wood subjected to the severest strains that it ever encounters, namely in aeroplanes, can be reliably seasoned in kilns. These results have been attained solely through the most careful research, involving the use of instruments registering the changes in temperature and moisture in kiln and wood, and including investigation into the causes of such defects as brittleness, case-hardening, collapse, explosive splits, and so forth. Not all woods are artificially seasoned with equal facility. For instance, the oaks among hardwoods and swamp cypress among softwoods require special and careful treatment; on the contrary, when compared with hardwoods, softwoods are more easily and rapidly seasoned, and can be safely exposed to higher temperatures, as their structure is less complex and their shrinkage generally less. Hence experiments are required to reveal the best, including most economic, treatment of timbers of different kinds and different dimensions. Even when wood and dimensions are the same the most economic treatment will depend on the use to which the wood is to be put, and the urgency of the demand; for instance walnut used merely for panelling can be exposed to much more rapid and drastic

seasoning at high temperatures than if it be intended for use in the propellers of aeroplanes.

Such investigations will certainly repay the expenditure of time and money, not alone in the resultant saving of time but also in the economy of timber. As regards the former, by kiln-drying the time of seasoning is reduced from years to months, and from months to days, or, for certain purposes, to hours. While, as regards economy of timber, Tiemann calculates that in the United States the losses of timber due to natural seasoning are five and more than twelve per cent. respectively in softwoods and hardwoods, and that these can be reduced to 2 per cent. In view of the fact that in certain types of kiln-drying waste steam may be used, the economic significance of these facts is doubly clear.

One method of introducing heat and moisture into a kiln is to supply steam. Drastic steaming at high temperatures permanently weakens wood, even it be relatively brief. On the other hand, prolonged steaming or "stewing" of wood in a confined space improves the qualities of woods in certain directions, in that it decreases their tendencies to warp and sometimes renders them more decorative by changing their colours; for instance, beech is thus induced to become somewhat mahogany-like in tint and in resistance to warping. This off-shoot of artificial seasoning provides an additional line of inquiry leading to the improvement in the qualities of inferior woods, especially from our tropical Colonies.

The seasoning of wood has yet one more important bearing on the economy of timber: it increases the resistance to decay. Decay or rot, in at least the overwhelming majority of cases, is caused by wood-destroying fungi, which demand for their development a certain amount of water.

The protection of wood from decay is a matter of great national importance. In our shallow and damp coal-mines, where the air is warm and moist, wood-destroying fungi are often so abundant and so active that timber is rendered useless in a few weeks or months. In 1913 the value of the imports of pit-timber into this country was nearly £4½ million sterling. An American investigator calculated that in the United States, if 40 per cent. of the pit-wood were treated with antiseptics, the annual saving in that country would be more than 50 million cubic feet of timber. I myself have seen a coal-mine in which the untreated pit-props had to be replaced in four to twelve weeks; whereas creosoted props side by side with them had already lasted for eight years. The neglect of adequate protection of wood from decay in this country is emphasised by the fact that I can secure no approximate estimates of the loss in pits, in buildings, fences and posts, or ships. The resultant loss must amount to millions of pounds annually, and much of that loss could be economically prevented.

Two methods, namely sanitation and antisepsis, offer themselves as means of decreasing or preventing the decay of wood.

As in pathological problems generally, and especially in epidemics, sanitation is in the end the cheapest method; but it demands a knowledge of the life-histories and conditions of activity of the organisms doing the damage. A few facts and examples may serve to illustrate the type of research that is urgently called for.

Fungi, which spread by means of their threads or microscopic spores, can be found growing in any house or damp coal-mine. Some of these are practically harmless, others actively destroy wood; it is therefore necessary to identify the fungi present, and to investigate their action in wood. After that the first practical problem in sanitation is to determine the source of the noxious forms, which may come from the forest, timber-yards, builders' yards, ships, or coal-mines, or elsewhere. The neglect of the elements of sanitation may be noted in builders' yards, where infected wood removed from houses is stored side by side with fresh timber and sometimes ready for incorporation into a new building. In a very large timber yard in London I have seen the fructification and spawn of the most virulent dry-rot fungus lying almost in contact with immense stacks of softwoods.

The fungi responsible for dry rot and decay generally vary in their demands for moisture. Some demand quite moist wood, and can readily be exterminated by ventilation and protection of the wood from wet; yet a few species, when once established, can manufacture water and thereby attack the driest wood. Some are readily killed by heat and cannot thrive at relatively high temperatures, others are more resistant to heat.

Again, certain species send their threads into the wood and spread internally at a slow pace, keeping at a distance from the surface. Cases due to this type of fungus are easily dealt with by removing the attacked piece of wood, whereas other species not only penetrate the wood but produce sheets or cords that rapidly

swoop over the surface of the wood, grow over and penetrate walls, and so transmit the infection through a complete building or roadway in a coal-pit.

Some species can attack only one kind or class of timbers, so that sanitation may take the form of avoiding the use of these. Other species can destroy woods varying from pine to oak and even teak.

This last consideration brings forward the question of the natural durability of timbers, upon which experiments are essential from the direct practical point of view and because the investigation of the relative immunity of certain species may afford a clue to a cheap and simple method of increasing the durability of woods that normally possess little.

As an accessory to or a substitute for sanitation, timber may be protected by the use of antiseptics such as zinc chloride, creosote and its derivatives, and various other inorganic and organic substances. These differ from one another in their fungicidal efficiency, some being completely effective against all fungi, others being (in practicable concentrations) lethal only to certain kinds of fungi. Moreover, the durability conferred depends upon the depth to which the antiseptic penetrates. Hence the precise process (whether painting or injection under pressure) and the precise fungicide to be used will depend partly upon the length of time that the timber has to last. These will also depend upon the situation of the timber: creosote with its powerful scent and discolouring qualities cannot be used in dwellings; whereas zinc chloride is not eminently suited for superficial coatings out in the open as it readily washes off. The discovery of cheap antiseptics suitable for various situations is a line of research of such fundamental importance as to be worthy of patient chemical and mycological investigation.

Time forbids my entering upon the less familiar but not unimportant question of protecting wood on land against boring insects, and of timber in sea-water (in piles, docks, etc.) against boring marine animals.

Just as the antiseptic treatment of wood renders possible the replacement of valuable durable timbers by cheap perishable ones, so likewise does the *fire-proofing* of wood subserve economy by permitting thin pieces of inferior wood to be substituted for thick pieces of more costly wood; specifications demanding that the doors of buildings shall be made of teak of great thickness are therefore extravagant, even though decorative. Investigations have rendered possible the fire-proofing of wood to such an extent that even thin three-ply can be made to resist for minutes or hours a temperature of 3000° Fahrenheit. The process of satisfactory fire-proofing is, however, not a cheap one, as the cheaper substances used are apt to wash out, to attack metals, and even favour the development of decay-inducing fungi. A problem of vital importance to builders, and even to the Empire, is the discovery of a cheap solution that shall simultaneously protect wood against decay and fire, and shall be suitable for use in dwellings.

Another method of improving woods, and especially those of inferior quality, is that of changing their colours and thereby improving their decorative value. By this means unmarketable colonial woods may be rendered of use. Such changes may be induced by steam, by chemical treatment with vapours or solutions, by treatment with dyes, or finally by exposing the wood to the action of fungi or bacteria. Except as regards the production of fumed oak by ammonia vapour, this branch of industry has been neglected in this country, which imports such stained woods as grey sycamore, artificial ebony (for piano-keys, knife-handles, and so forth).

As an illustrative case, reference may be made to grey sycamore, which is obtained from ordinary white sycamore by means of simple and cheap chemical treatment. Yet for years white sycamore was exported to Paris and Hamburg for treatment, and re-imported into England at an increase of price perhaps fifty times the true cost of the process. Great Britain does, however, export one unique type of coloured wood, brown oak, which, owing to its richness of tint, is much more valuable than the ordinary British oak. At the Imperial College it was discovered that the brown colour is induced by a fungus, and that by growing the latter upon ordinary oak this is converted into the brown wood. It would doubtless be possible to devise a method by which this exceedingly profitable conversion could be conducted on a commercial scale.

The chemical utilisation of wood forms too wide a subject to be dealt with except by allusion. As a means of using up waste wood (sawdust, shavings, slabs) in the sawmill, or waste trees in forests of the Colonies, mention may be made of the destructive distillation of wood, which thus becomes a source of methyl alcohol, formalin, acetic acid, acetone, and charcoal. In countries having feeble supplies

of coal this same process can be made to yield illumination and power. Other problems concern the most economical manner of using waste wood directly as a fuel.

In connection with several lines of investigation, mention has been made of the utilisation of waste wood, and in order to illustrate the fact that this alone represents a problem of national importance I will mention that in this country there is one single wood-using establishment in which the normal annual loss or wastage of timber represents a sum approaching £20,000.

For the purpose of demonstrating what the British Empire has done and is doing in the way of forwarding technical knowledge relating to timbers, I will compare its activities with those of two other great Powers, the United States and Germany.

Although France produced the first model investigations on the mechanical properties of wood, Germany in recent times has done a large volume of excellent work and correlated the results with the structure of timbers concerned. Along the two lines she has been ably seconded by Austria, and these two partners have conducted minute and detailed research on timber-structure from the point of view of identification. To Germany more than any other country we owe our modern knowledge on the fungi inducing decay in timber, and on modern antiseptics suited for combating them. Germany, together with Austria, has largely contributed to the development of the technical art of changing the colours of woods by chemical means and by dyes. Her work on the utilisation of wood as a fibre material, as fuel, and by destructive distillation has given to her the leading place in these fields.

Germany has, in addition to her forestry schools, various institutes from which emanate the results of researches in the various branches of the subject. And the State has founded, staffed and equipped, an institution whose sole function is to investigate the problems of the decay of timber and its prevention.

Germany thus spends thousands of pounds annually on timber investigation. She also promotes the use of her colonial timbers by this means, and by describing or referring to them even in small text-books.

The United States has produced many valuable results on the mechanical properties of North American timbers, and on technico-practical questions concerning American woods as sources of fibres and of chemical bodies. Her workers have also published much detailed original information on the structure and identification of the indigenous timbers. While in one branch, that of artificial seasoning of wood in kilns, the United States leads the world in original investigation and practical invention.

Apart from possessing some forestry schools, the United States has one institution specially founded for the investigation of timber problems, namely, the Forest Products Laboratory, at Madison. I believe that the annual sum paid for researches in this laboratory exceeds £40,000. This laboratory works in close touch with men engaged in the timber trade. And the timber trade journals published in the United States give, by the very nature of their articles, sufficiently clear evidence of the intimacy of the relations between wood industries and technical science.

Great Britain doubtless was handicapped by the lack of any great forests that should stimulate research of the highest type on the mechanical qualities of timbers. First-class original work up to modern standard has never been produced in this country on this branch; the work done has been narrow in scope, because done by engineers, who even to-day are profoundly ignorant of the basic facts on the subject of wood-structure. The sole comprehensive modern researches on the mechanical properties of wood conducted in the British Empire emanate from Australia. In regard to the structure of timber this country has contributed little, except fragments concerning colonial woods. But in India Mr. Gamble has produced a great work on the macroscopic structure of Indian woods. Although England at the outset led the way in providing antiseptics and means of injecting them into timbers, her original scientific activity in this direction ceased decades ago; while as regards the investigation of the fungi causing decay in timber our Empire has done practically nothing.

Altogether, famous as this country has been in the past from the practical standpoint as regards timber, she has been a nonentity as a contributor to the scientific technology of wood. The time has past when it is safe to continue such a policy.

In the United Kingdom, although there are some incipient schools of forestry, and there is a professor of the technology of woods at the Imperial College, the State neither maintains any technical authority on timber in its employ

nor devotes any sum to research on the subject. The timber industries likewise have no technical consultants nor do they subsidise research. Hence, where the Governments of the United States and Germany spend annually thousands of pounds on timber-research conducted by specialists, our Government spends not a penny, though the wood imports amount in value to more than forty million pounds sterling annually. The Forest Research Institute in India, and Forest Products Laboratory in Canada, represent the official provision made by the British Empire for the investigations on woods coming from forests that are larger in extent and variety than those governed by any other State in the world, and whose value must be reckoned in hundreds of millions of pounds.

But there are signs of awakening as regards research. The awakening is Imperial, not merely national: and this is of vital importance because this country and the remainder of the British Empire should be linked together in policy as regards the great timber problem of the future, and therefore linked together in attacking the problems whose solutions will dictate that policy and will indicate the best method of utilising our common timber resources. In this country and in Australia Departments of Scientific and Industrial Research have arisen, and it is to be hoped that the great trades will also take part in this forward movement, for the greatest advances can be achieved solely by the co-operation of the State, the trade, and the technical specialist —and this is especially true of the great timber industry.

DISCUSSION.

THE CHAIRMAN (Professor William Bateson, F.R.S.) said the paper provided a great many subjects for thought on a great variety of topics. The point that had impressed him most was the apparent hopelessness of trying to keep up with the supply of timber required by the life of modern civilisation. It appeared that we were in the same position with regard to timber as we were with regard to coal and rock oil, namely, that we were living on our capital and that, however we managed the existing supply, we should not have enough to meet the needs of the present population. In the case of wood used for paper, for example, destruction was going on very quickly, even though the Governments of the various countries concerned were doing their best to promote production. He had himself seen the lamentable picture the landscape in Australia presented, where one could travel for hundreds and even thousands of miles through country consisting almost entirely of dead trees, magnificent trees which had been killed by the early settlers in the hope that they might have one sheep to every three acres on an average. It would take something like a thousand years to replace those trees. A great deal could be done to promote the production of timber, but he would like to know whether the author thought it would ever be possible to produce the quantity of wood that the population of the earth at present required.

MR. A. L. HOWARD thought the paper was a sufficient answer to the gentleman who, when Professor Groom read a paper before the Aeronautical Society in that room, said that scientific research was of no use with regard to timber, and that what was wanted was the advice of practical men who understood timber. The paper contained a great deal of food for reflection for the practical timber expert. With regard to the quality of the timber grown in England, until the previous autumn he did not know that timber grown in the south of England was not only as good as but considerably better than some timber imported from the Baltic. He had seen Scots pine grown in the south of England which, in freedom from knots and sap, was superior to a great proportion of the timber that had come from the Baltic. In that connection he might mention that, whereas the price allowed to be paid for the foreign article at the present time approached 8*s*. per foot cube, the price which was allowed to be paid for the British-grown product, whether it was of the highest possible quality or of the lowest possible quality, did not reach 4*s*., or half that of the foreign article. He thought that was a continuation of the policy adopted in the past, which had led to the deplorable results witnessed at the present day. Twenty years ago the Arboricultural Society appointed a Rates Committee, of which he was a member, and he found that Germany carried foreign timber inside her borders at a rate which was many time greater per foot than the rate at which she carried her home-grown product. Germany also gave a premium to everybody who would use the home-grown product, and she made it difficult to use the foreign product. The Committee found that in England it cost as much to bring timber from Liverpool to London by rail as it cost to bring it from a thousand miles in the interior of America and across the Atlantic into London. The second point in the paper which he thought was particularly worthy of remark was the number of tests which Germany had made in regard to the quality of timber. He assumed that the author's remarks in that connection applied only to Scots pine, because in this country we knew the mechanical values of many of our timbers other than the Scots pine. With regard to the question of the name of the timber imported from the West Coast of Africa and sold under the name of "mahogany," and the harm that has been done to this country and the benefit that had ensued to Germany thereby, he did not think the author's explanation was quite correct. He was afraid the real reason why the wrong names were given to timbers was because of the want of

scientific research and knowledge, and of any attempt to bring to the front the proper way of dealing with woods and their names, and because of the looseness of our laws in connection with the matter. For instance, for many years past large quantities of so-called Austrian oak had been supplied in this country which consisted of other kinds of oak, and yet the timber had been accepted and used. Then again, certain teak was called "Borneo teak," although he thought it was a fact that there was not and never had been any teak in Borneo. While teak possessed an essential oil which was preservative to itself and to everything with which it came into contact, the wood which was called teak and sold as teak possessed an essential oil which was harmful to itself and to everything with which it came into contact. The same point applied in connection with many other woods. For instance, it had been found impossible to sell the sweet gum of America under the name of "gum," and it had been called successively satin walnut, hazel pine, and Californian gum. The mixing of woods was generally to be traced to tradesmen, who gained a benefit by so doing, and there were apparently no laws or societies or associations to protect the users. With regard to the question of sending timber to be coloured in Paris and Hamburg, the British public would not buy coloured woods very readily; the demand for them in this country was very limited and uncertain, and it was therefore not worth while establishing plant to any extent. The cost of freight to and from Paris was very small, and the process of dyeing adopted there was very beautifully performed. If there had been a greater demand in this country for coloured woods, no doubt that demand would have been met by the establishment of plant on a larger scale. He did not agree with the author's remarks about the economy practised by this country in the use of timber, because he thought we were the most extravagant people in the use of timber that the world had ever seen. If a comparison was to be made of the consumption of wood in different countries, the varying circumstances and necessities of those countries must be taken into account. For instance, the population of the United States as compared with its area was very different from that of Great Britain, and many farmers in America and Canada built their houses of wood. A comparison could not be fairly made between the amount of timber such men required and the amount needed by men living in brick houses in London. The extravagance in the use of timber in England, especially since the war began, was positively criminal, and he was afraid the Government was the greatest offender. A contract had recently been put out by the Government for field telegraph poles about 8 feet or 12 feet long and $1\frac{1}{2}$ or $1\frac{3}{4}$ inches in diameter, and the contract provided that a sum of about £7,000 should be expended on Oregon pine at something exceeding 8*s*. per foot cube for those poles. Before the war clean, straight-grained Oregon pine could be obtained for about 1*s*. 6*d*. or 1*s*. 10*d*. a foot, and then perhaps it was the best timber that could be used, but why should 8*s*. per foot cube be paid now for Oregon pine for field telegraph poles when those poles could be just as well made of white spruce or Scots pine or larch, for which the Government would not allow anyone to pay more than 10*d*. per foot? It must also be remembered that that Oregon pine at 8*s*. per foot cube was of doubtful quality, because, if that was not so, it would have been worth 24*s*. per foot cube for aeroplane work. Then, again, he had seen maulheads made of beautiful timber brought from abroad at a cost of about 12*s*. or 14*s*. per foot cube, when British elm would have done perfectly well. Lastly, what about the policy of a Government that established an enormous Timber Department for the purpose of economy in supplying timber? Such a department might be necessary, but it certainly was not economical. He did not think any Government Department in this country was ever carried on on economical lines.

Mr. Hugh Davies said he wished, as a member of the Department of Scientific and Industrial Research, to make some defence against Mr. Howard's criticism that Government Departments were not economical. The Department of Scientific and Industrial Research was concerned with economy in the use of timber, and hoped shortly to be in a position to do a great deal in assisting the public to economise in that direction. Lack of economy in regard to timber did not always arise from pure waste of timber, but from failure to use the material to the greatest advantage in view of its particular properties. For example, when timber was used for building or engineering work it was customary to provide a factor of safety of about 10, as compared with factors of safety of 3 or 4 with other materials. At first sight it might seem that there was no alternative to such a course, in view of the results of tests made upon timber, but recent investigations with regard to the lamination of timber and to the use of timber in the form of plywood showed that there might be ways of using timber which would enable the factor of safety to be reduced to 5. That would mean the reduction of our expenditure on timber by something like one half, which would be a very substantial economy.

Mr. William Woodward, F.R.I.B.A., speaking from the point of view of an architect, said he had been very much impressed by the paper, and by the excellent practical remarks of Mr. Howard. With regard to the teak mentioned by Mr. Howard, he did not know whether the author could say why there was a very obnoxious smell from certain teak. He knew of a case where a city office had been fitted up with teak, at very great expense, and it all had to be removed owing to its unpleasant smell. Mr. Howard had also spoken of Austrian oak, and

in that connection he might say that architects had for many years been in the habit of using Austrian oak because unfortunately they could not use English oak for ornamental purposes. Architects did not know whether so-called Austrian oak came from Austria or from some other country, but they had used it because of its practicability for ornamental purposes. For many years past they had not been able to obtain the Spanish mahogany that they formerly specified for ornamental purposes, and one could only find real Spanish mahogany when one visited certain fine old-fashioned hotels in some parts of England. With regard to the fuming of wood mentioned by the author, architects only knew of the fuming of oak because of its appearance, but whether fuming was injurious to the wood or not he did not know. The fire-proofing of wood was of course a very important matter, but he could not say whether fire-proof material had withstood fire. The question of dry rot was of very great importance to architects and to their clients, and the means of preventing dry rot had occupied the attention of the Royal Institute of British Architects for many years. It was sometimes said that dry rot could be prevented by efficient ventilation. When it ensued, however, the fungus spread very rapidly, and in order to preserve the timber from further inroads of dry rot various expedients had been employed. If the author could tell the Institute of British Architects how they could, in the construction of a new building, prevent future dry rot, he would do a very great service to architects and to their clients. With regard to seasoning, that was sometimes induced by artificial means, which he had always understood to be very deleterious. He believed that seasoning by heat killed the wood and led to premature decay, and that it ought to be entirely avoided. Formerly timber yards were often seen where the timber was drying with spaces between it in a natural way, and although that method was not adopted so frequently at the present time he believed it was the proper way to season timber.

Dr. J. A. Voelcker said the paper illustrated a story to which the people of this country had become pretty well accustomed in other industries besides the timber industry—the old story of ignorance and neglect, and the need of further scientific research, and the encouragement of that research by the Government. It appeared that this country had made a start in one or two branches, but that other countries had got ahead of us, and one very potent reason for that had been the want of scientific research, and of Government encouragement to that research. He was glad to think that in the matter of forestry there was a sign of some change in this country. He wished to put in a plea for the landowner, because he did not think that in the past the landowner had been altogether to blame. He remembered that about thirty years ago he stayed with a friend who had an interest in a colliery in the Midlands, and who had a quantity of wood on his own property quite near the colliery. That friend told him that it cost him more to cut up his wood and use it for pit-props for his colliery than it did to get the pit-props from Norway and Sweden; therefore there was no reason for him to encourage the growth of timber. If a landowner did anything in the way of forestry future generations would reap the benefit of it, and the chance of his seeing any return for his money was not very great. He thought a change was about to take place, however, as was indicated by the shows of the various agricultural societies of this country. The shows of the Royal Agricultural Society indicated that a great and increasing interest was being taken in the subject of forestry, and many points of interest, some of which had been mentioned in the paper, were being brought out in connection with those shows. The author had given concrete instances of the need for scientific research in the direction in which it might be rightly exercised. He had spoken, for instance, of fungi, and had said that fungi were very much like bacteria—they were not necessarily all bad, and some were even beneficial to timber. Two important subjects for research were the preservation of wood by antiseptics and the rendering of it fireproof.

The Earl of Powis said he would like to know what Mr. Woodward meant by the statement that it was impossible to use British oak for ornamental purposes. Personally, if he wished to use oak for ornamental purposes he would certainly specify British oak. He knew that for many years past a great many architects had been opposed to using British timbers, and had stated in their specifications that foreign timbers were to be employed, but he thought that was due, to a great extent, to the difficulty of obtaining exactly the quality of timber that was required at the moment and not to the fact that it was not growing in the country. He thought British timber ought to be encouraged a great deal more, and architects were the people who could best give that encouragement.

Mr. William Woodward, F.R.I.B.A., said that the reason why he did not specify the use of English oak for ornamental purposes was that, although he had always used it for posts, gates, and other things outside the building, he had found that it was quite unfitted for ornamental panelling inside the building, because of its splits or fractures. English oak did not preserve its evenness of texture in the way that Austrian and other oaks did.

The Earl of Powis said that in his own house, where nothing but British oak that had been seasoned for fifteen years was used for the panelling, not one single crack had appeared in any of that oak.

The Chairman, in proposing a vote of thanks to the author for his interesting paper, asked whether the teak which the author mentioned as suffering

from fungi was real teak or not. He was under the impression that the oil to which the smell of teak was no doubt due acted as a strong antiseptic against fungi.

The resolution was carried unanimously.

PROFESSOR GROOM, in reply, said that, with regard to the quantity of wood in the world, his reason for particularly urging the use of tropical woods where possible, especially in reference to fibre-making, was that with every rise in temperature the rapidity of chemical action increased, and, therefore, as that held good with regard to trees, if people wished to employ wood economically they should grow it in the moist tropics of Africa and America. He had never considered the question of whether timber could be grown in sufficient quantities to meet the demand, but it was a most interesting problem. He thought it could be done very easily at the present time. The reason why he mentioned teak as subject to dry rot was because it was such a resistant wood, and yet when the fungus *merulius* had obtained a start in soft wood it could attack and destroy good teak. With regard to the disagreeable aroma of teak, he did not know the cause, but every practical man knew that when teak had been sawn up it often smelt very unpleasantly, and it was also known that in Siam teak logs were sometimes stored for weeks or months in extremely unsavoury mud close to the native villages. He cordially agreed with Lord Powis's opinion as to the quality of British oak and its superiority to every other type of oak from a decorative point of view, although it was harder to work and more liable to split. Anyone who went to the Court of Criminal Appeal and examined the panelling there, which was made of British oak, would agree that it was the finest modern panelling one could find anywhere.

The meeting then terminated.

MR. A. L. HOWARD writes:—It is fortunate that the Earl of Powis dealt with Mr. Woodward's statement that it was impossible to use British oak for ornamental work, partly because it could not be obtained and partly on account of its liability to split, etc. Had I not felt that I had already spoken at too great length, I should have wished to refer to this subject on account of its national importance. For the past twenty years many timber firms have followed the practice, which I think I may claim to have originated, of manufacturing and storing very large quantities of the highest possible quality British oak in the way required to overcome the objections raised by Mr. Woodward, which were originally due to the ignorance and apathy of the British timber industry. In the opinion of many, no foreign oak—either Austrian or any other—could for a moment compare in beauty, durability, or value with the British. We realise this when we stand before the exquisite old panelling in some ancient building such as Haddon Hall in Derbyshire, Marks Hall, Coggleshall, in Essex, or the superb room taken from a palace at Bromley-by-Bow, now in the Victoria and Albert Museum. For variety of grain, sense of solidity, but more than all for richness and warmth of the right tone of colour, what is there to compare with it? Strange it is in an age when the revival of design and architecture has made such strides that so few have realised the rare beauty of British oak work. In the past our supplies have been more appreciated in America than at home, but there still have been many fine specimens of work, especially of later years, and I beg I may be excused if I venture to catalogue some of these with which I have been acquainted, where I have personally selected the timber in some cases with my own hands. They are as follows:—

The Thistle Chapel at St. Giles', Edinburgh, designed by Sir Robert Lorimer, and built by Mr. N. Grieve. The British oak used in this building was over fifty years sawn and sticked and was grown in Essex.

Liverpool Cathedral, designed by Mr. A. Gilbert Scott, also supplied from the same wood as above.

The dining-room of a house at Hyde Park, the work executed by Holland & Hannen, being a reduced copy of Brewer's Hall.

The new buildings of the Law Courts, executed by T. H. Kingerlee & Sons, Oxford.

The sub-committee room and other rooms at Lloyd's Registry, designed by Collcutt & Hamp and built by J. Mowlem & Co. The sub-committee room is one of the most beautiful examples of British oak work, and was furnished from timber grown in Essex and Northampton.

Also by the same Architects, the offices of the P. & O. Co. in Leadenhall Street, and Sir Thomas Sutherland's house in the country. This gentleman, with the architects and others, has probably contributed to the advantage of his country and the history of the future by insisting (on some occasions not without opposition from some quarters) that the P. & O. Co.'s steamers should be trimmed with English oak.

Mr. G. T. Wills' house at Sunningdale, built by J. Bentley & Sons, Waltham Abbey. The timber used here was mostly grown on Lord Chesham's estate at Latimer.

Mr. T. E. Collcutt's house at Totteridge, Herts, possesses a superb hall and room.

Mr. Alfred B. Smith, The Crossways, Totteridge, Herts, has a similar hall and staircase.

The Lynch House, Totteridge, Herts, possesses a hall and staircase made from oak entirely grown in the hedgerows at Totteridge Park.

Highwood, Highwood Hill, has a fine hall and staircase in British oak executed by J. Simpson & Son.

Much of the above work in British oak, and a good deal more, was made by John Ayton, originally of

Dunmow, in Essex, who is an artist in this work, but who, I hope, would not be offended at being called a village carpenter. I mention this here only because of the prevailing idea that it is too difficult to carry out decorative work in British oak.

At Newberries, Radlett, occupied by Mr. George Miller, there is a handsome British oak hall executed by J. Simpson & Son.

A superb building in Bedfordshire was lately erected by Holland & Hannen for Mr. Clutterbuck in all British oak.

I could mention a great many more, but will content myself by referring only to Armament Buildings, Whitehall. The Government specified that this work was to be executed in Austrian oak, after the war had broken out in 1914. Fortunately the authorities altered it to British, and two beautiful rooms were provided by H. C. Cleaver, Ltd., of Wembley. A brass tablet is displayed on the panelling giving the botanical variety and place of growth of the oak used.

It might not be out of place here to refer to a note in the Blue-book of the Westminster Hall roof:—

a. The timber should be open grown oak in park situations or grown as coppice and standard.

b. The soil in which the timber is grown should be known, and should be a stiff retentive loam.

c. The species should be the *pedunculata*: sessile or durmast oak should not be used.

e. The timber should be at least two to three years fallen before converted. . . . Timber merchants, as a rule, can give no information as to the species of oak from which the timber has been cut. In addition they have no note of the soil on which it has been grown, nor would they appear to have very definite records as to the time of felling. Their general attitude is: "Here is my supply of oak, I have got a large market for it, so you can take it at my price or leave it."

folio 43. Report to First Commissioner of H.M. Works, *re* Westminster Hall.

I do not agree with any of these remarks. The greatest known authority on the subject of British oak, and the man who probably had the most extensive practical experience, says:—

"It is the prevailing opinion that the wood of the *Quercus Robur pedunculata* is the best in quality, and that the *Q. Robur sessiliflora* is slightly inferior to it, but while concurring generally in this opinion, I feel bound to admit that, during a long experience in working them, I have not been able to discover any important difference between the two varieties."

folio 43/44. Timber and Timber Trees, Laslett.

Having studied this question closely for many years, I agree with Laslett that it is impossible to distinguish between the wood of the two botanical varieties. The utmost that can possibly be said is that the product of *Q. sessiliflora* is on the whole somewhat milder in the grain, but as by far the principal supply of the country consists of *Q. pedunculata* it cannot matter much, as no work to any extent could be carried out if only authentic supplies of *Q. sessiliflora* had to be used. I am also of opinion that it is quite immaterial to know where the timber has come from, or of what the botanical variety consists, as those who know timber can judge at a glance of the suitability or otherwise of its quality without further inquiry. The really important question is how it is cut, manufactured and stored. Here, again, I find myself at variance with the Westminster Hall Blue-book. I am persuaded that for the trees or logs to remain for any period before conversion is bad, and the longer they remain the worse it is: trees under such circumstances are open to the attack of all kinds of fungi and boring insects. Large cracks and defects result from the uneven action of shrinkage, where insects can penetrate and the fungi thrive. It is only after many years perhaps, when the timber has been placed in position in the building, that the damage becomes apparent. The waste in conversion is largely increased, and no real seasoning of the timber can take place. Trees should therefore be sawn into planks and boards immediately after felling, and the manner of conversion should be studied in accordance with the circumstances and the probable requirements of the timber. Among the many disadvantages from which British-grown timber has suffered in the past, not the least has been the utter lack of thought and trouble in felling, conversion and subsequent handling. In other countries the absolute necessity for fostering the trade has resulted in better practices, and in no case is this better illustrated than in the forests from whence so-called "Austrian" oak has been produced.

OBITUARY.

Edward Cookworthy Robins, F.S.A., F.R.I.BA.—Mr. Robins, who died on June 18th, at the age of eighty-seven, became a member of the Society in 1870, and served on the Council from 1887 to 1890, when ill-health compelled his retirement from all work, public and private. As a member of the Court of the Vintners' Company he took an active part in the movement for the promotion of technical education in the City of London, the result of which was the establishment of the City and Guilds Institute. In 1882 he read a paper before the Society on English and Foreign Technical Education. In the same year he was appointed by the Council Architect to the Society, and in that capacity took charge of the renovations and improvements made in the meeting-room and the library, including the ventilation of the former. He had a considerable practice as an architect from 1858 to 1890. Among his executed works were Weeley Church, Essex, the Camden High School for Girls, the Bedford Grammar School, and the Merchant Venturers' School, Bristol. He was one of the pioneers of modern sanitation, took great interest in, and designed the fittings for, science schools and laboratories, and published a book on the subject.

THE SECRETARY, John Street, Adelphi, London, W.C.

HOWARD AND OTHER LECTURES.

Heavy Oil Engines. Four Lectures. By Captain H. Riall Sankey, R.E., M.Inst.C.E. (1912.) Price 1*s.*

Aeronautics. Three Lectures. By Prof. J. E. Petavel, D.Sc., F.R.S. (1913.) Price 1*s.*

Surface Combustion. Three Lectures. By Prof. William Arthur Bone, D.Sc., Ph.D., F.R.S. (1914.) Price 1*s.*

Motor Fuel. Three Lectures. By Prof. Vivian B. Lewes, F.I.C., F.C.S. (1915.) Price 1*s.*

Coal and its Economic Utilisation. Three Lectures. By Prof. John S. S. Brame. (1917.) Price 1*s.*

The Shortage of the Supply of Non-Phosphoric Iron Ore. Two Lectures. By Prof. William George Fearnsides, M.A., F.G.S., M.Inst.M.E. (1917.) Price 1*s.*

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

All communications respecting Advertisements should be addressed to the ADVERTISEMENT MANAGER, 97, Gresham Street, E.C. 2.

FRIDAY, JULY 12, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

CHAIRMANSHIP OF COUNCIL.

On Monday, the 8th inst., at their first meeting in the new session, the Council re-elected Mr. ALAN A. CAMPBELL SWINTON, F.R.S., Chairman for the ensuing year.

PROCEEDINGS OF THE SOCIETY.

TWENTY-SECOND ORDINARY MEETING.

Wednesday, May 29th, 1918; SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Basden, Duncan Frederick, London.
Forbes, David MacHattie, Hawaii.
Highfield, John Somerville, M.Inst.C.E., M.I.E.E., London.
Liversidge, Engineer-Captain Edward William, R.N., Bermuda.
Prosser, John, Greenwich.
Shipley, Rev. Samuel Paul, F.R.Hist.S., Oakham.
Taylor, Charles Wardrope, South Shields.
Vyle, Gilbert Christopher, Birmingham.
Wisnom, Engineer-Commander William McKee, R.N. (retired), Cardross.
Wordingham, Charles Henry, M.Inst.C.E., M.I.E.E., Redhill.

The following candidates were balloted for and duly elected Fellows of the Society:—

Barouch, L., London.
Brown, George, Greenock.
Clapperton, George, Oxford.
Claus, William Henry, Alderley Edge.
Fryer, Frederick George, M.I.Mech.E., York.
Pugh, Ralph John, London.
Talbot, Benjamin, Middlesbrough.
Taylor, Alderman Herbert, J.P., Eaglescliffe, Co. Durham.

The paper read was—

ORGANIC CHEMISTRY IN RELATION TO INDUSTRY.

By DR. M. O. FORSTER, F.R.S.,
Treasurer of the Chemical Society; a Director of British Dyes, Ltd.

Prominent among the industries which have been pursued with unflagging activity since the outbreak of the world-war is that of criticising our fellow-countrymen. Instruction of other people in the art of reforming the conduct of their affairs has always appeared an attractive exercise to the average Englishman, and probably each one of us must plead guilty to having practised it at one time or another. It seems to be a simple task, and in performing it we are plentifully endowed with that wisdom which comes after the event; moreover, in reviewing the shortcomings of our victims we are frequently ignorant of the difficulties which beset their path, and of the time and energy which have been absorbed in surmounting the common physical and psychological obstacles which present themselves in the daily routine. In a word, we are too much inclined to judge men in the light of how we should wish them to behave, rather than to accept them as experience of life has taught us that they do behave. It is not my purpose in this paper to swell the volume of fault-finding, but I do desire to entreat once more for the recognition of organic chemistry as a vital factor in the successful prosecution of British industrial enterprise.

If there is one lesson which, more than any other, has been taught by the discipline of war, it is the need of being self-contained. In regard to food-supply the U-boats have shown themselves to be the most energetic missionaries of this gospel, and do not require assistance in their adventure. Board of Trade statistics will show to what extent the textile industry, except in regard to wool and jute, is dependent

upon foreign countries for its cotton, hemp, silk, flax and wood-pulp. All these raw materials resemble one another in being almost literally raw materials, that is to say, natural products upon which but little labour has been expended besides that required for cultivation and collection, followed by transport to manufacturing centres; but the textile industry depends also upon a raw material which is to this extent peculiar, that it includes numerous products of highly skilled workmanship, arising from an auxiliary industry which is more complicated than any other. You will immediately recognise this raw material as comprising the vast range of synthetic dyes, and it is because of this exceptional relation to the textile industry that aniline-colour manufacture has come to be called a key-industry, controlling, as it does, an industrial output approximating in value to one hundred times its own.

It must be remembered that aniline-colour manufacture is only one branch—although a very important one—of the organic chemical industry. The production of explosives, illuminating and fuel oils, natural and artificial remedies for disease, photographic materials, margarine, soap, rubber, perfumes, artificial silk, and celluloid, whether inflammable or non-inflammable, is intimately connected with the principles and practice of organic chemistry, whilst the production of spirituous liquors, dairy produce, meat extracts and cereal foods has undergone marked improvement in consequence of applying this branch of knowledge to its control. The general public, however, so far from realising their debt to organic chemistry, would be puzzled to find a definition for it, and this they owe to the tardiness with which even the highest educational authorities have recognised it as a distinct branch of science. Until quite recently the colleges and universities have placed organic chemistry in a secondary position, marked by leaving instruction in the subject to a subordinate member of the staff. Happily this deficiency is gradually being made good. Manchester, indeed, has had a professor of organic chemistry since the days of Schorlemmer, but a similar post was not established at University College, London, until 1902. The example was followed by Leeds in 1904, Oxford in 1913, the Imperial College of Science and Technology in 1914, and Liverpool University in 1915. The Universities of Aberdeen, Belfast, Birmingham, Bristol, Dublin, Durham, Edinburgh, Glasgow, St. Andrews and Sheffield still possess only one professor of chemistry apiece, however, and it is left to chance, assisted by the appointments committee of the respective body, to determine whether a new occupant of the chair displays organic or inorganic proclivities.

When contrasted with the corresponding situation in Germany, this record is one which goes far towards explaining our admitted inferiority in this branch of science. *Minerva* for 1913–14 discloses the fact that the twenty-one German universities were provided with 108 professors of chemistry, an additional forty-nine representing the senior chemical staff of the nine technical high-schools. In Great Britain and Ireland there were eighteen universities with thirty-five professors of chemistry, nine further educational institutions having amongst them twelve such professors, making a total of forty-seven, compared with the German total of 157. In proportion to the difference in the population of the two countries, it might be stated that Germany has only twice as many professors of the subject as are to be found here, but this would give a false impression of the facts. It is less illusory to consider the position from another standpoint, namely, that a population half as large again as that of the United Kingdom has been influenced by the instruction and inspiration derived from a body of teachers three times the number of our own; from this it follows that, even assuming equality of receptivity as between the students, and of capacity as regards the teachers, the output of German chemical talent may be estimated at between four and five times that of this country per annum. Remembering that this disproportionate effort has been operating during a period of many years, we cannot be astonished that the present relative position of the two countries in the matter of chemical achievement has been reached.

Quite apart from the material fact that, when applied to the numerous industrial processes which it underlies, organic chemistry has been highly remunerative, I claim that it offers one of the most attractive available agencies for cultivating the human intelligence, for the man who devotes his life to this branch of scientific study may incidentally satisfy most forms of intellectual craving. Since this claim has been obscured in the past, it may be worth while to review the evidence which supports it.

The first mental demand of which we become aware is for romance, and as in some

respects we nearly all remain children for most of our lives, this need survives until death. Carefully studied, the history of synthetic dye manufacture, which has been more than anything responsible for the development of organic chemistry, is highly romantic. The accidental discovery of the first one by a lad of eighteen, who forthwith laid the foundation of a profitable commercial enterprise; the discovery of magenta in France, also fortuitous; the dazzling prosperity of Simpson, Maule and Nicholson; the gloomy failure of their successors, Brooke, Simpson and Spiller; the discovery of the diazo-reaction by a peasant-student; the twenty-four hours' interval between the Caro, Graebe and Liebermann patent in Germany and the Perkin patent in England, for the manufacture of alizarin; the consequent elimination of madder from among the products of agriculture; the persistent German efforts to elucidate the constitution of indigo and to base thereon a process for its commercial synthesis; the complete and profitable triumph of these; the consequent decay in the cultivation of natural indigo; the also consequent development of the contact-process for sulphuric acid manufacture; the improvements in the production and storage of chlorine, and the diabolical misuse of this material in 1915, are some of the salient incidents in the life of a great industry. A study of these, and of many more which cannot here be considered, a calculation of the part which each has played, and a just appreciation of the men connected with them, would furnish material for one of the most absorbing and fascinating histories of triumph and tragedy yet remaining to be written.

Methodical habits are not so widely diffused as we might wish, but happily there exists in many people a desire to be precise and orderly. Systematic organic chemistry is the crystallisation of orderliness. When the study of carbon compounds first began to attract attention one hundred years ago, scarcely fifty of these materials were known to chemists, and among them there appeared no order, no relationship. At the present time more than 200,000 are known, their number increases each day, and all are capable of being relegated to some clearly-defined group by the simple process of reviewing their origin and their properties. The number of such groups is comparatively small, but the relationships between them are well understood, and it is a mere statement of fact that there is more order among the 200,000 than there was among the original fifty.

An appeal is also made by organic chemistry to the creative instinct and to the imagination which, in some form or other, are found implanted in the mind of every civilised man. One hundred years' study of carbon compounds has revealed a bewildering variety of processes by which this element may be brought into combination, principally with hydrogen, oxygen and nitrogen, to a minor extent with chlorine, bromine, iodine, sulphur or phosphorus, and indirectly with almost every other elemental form of matter. These processes of combination are the weapons in the hand of the chemist by means of which he is able to bring about new atomic arrangements, leading to compounds which have never been built up before, or which have been constructed only under the guiding influence of living animal or vegetable organisms. In this manner the existing 200,000 organic compounds have been brought to light, and the possibilities being by no means yet exhausted, the combinations remaining to be achieved continue to attract the synthetic-minded chemist to the task of realising them; in this exercise imagination plays a most important part by devising the frame-work of theory upon which the practical details of the science are laid.

Two examples of this principle may be usefully quoted. Prior to 1865, a confusing number of materials derived from the coal-tar hydrocarbon benzene had been accumulated, devoid of any system by which the relationship of the substances to one another could be explained. The structure of most compounds not derived from benzene or similar hydrocarbons could be represented on paper by diagrams in which the carbon atoms appeared as links in a chain, these chains being short or long according to the number of carbon atoms involved in their construction. Sometimes the chains were straight, and sometimes they were branched, but they were always open at both ends, and the compounds they represent have come to be known as "open-chain" compounds, or, because the earlier members of the series were derived from fats, as fatty compounds. On these lines, however, there was no theory to explain the constitution of benzene derivatives until, in 1865, a very simple hypothesis suggested itself to the German chemist Kekulé, who had noticed that in these derivatives there were never fewer than six atoms of carbon. He imagined these six atoms as forming links in a chain which differed from former chains in being closed at both ends

to produce a ring, or "closed chain": thus benzene itself, with six carbon atoms each combined with an atom of hydrogen, has come to be represented symbolically by a regular hexagon. The result of this exercise of imagination was magical. All those accumulated materials derived from benzene, the relationship of which had been unintelligible hitherto, arranged themselves in orderly compartments, and the two great classes of organic compounds came to be more strictly defined as fatty or open-chain, and benzenoid or ring compounds. Progress has demanded certain slight modifications of these groups, but it is not an exaggeration to say Kekulé's theory of benzene constitution gave to organic chemistry a new lease of life, since it not only established order where formerly was chaos, but it furnished both foundation and incentive for many of the most fruitful chemical investigations of later days.

The second great example which illustrates the use of imagination in the study of organic chemistry is to be found in the theory of the asymmetric carbon atom, usually associated with the name of the Dutch chemist van't Hoff in the year 1874, but owing even more to the celebrated Pasteur, the founder of bacteriology. Here again the effect has been to clear away an accumulation of puzzles and obscurities, to lay the foundation for more stable classification, and to furnish a mental stimulus for fresh investigations : it lifted the chemical mind out of two dimensions into three.

Whilst the creative instinct, in its intellectual aspect, leads to exercise of the imagination, its physical expression is found in the development of manipulative skill or craftsmanship, and this craving, strong in most of us, may be fully satisfied by the pursuit of chemistry. A modern laboratory needs to be equipped with an immense variety of apparatus and materials, the use of which demands patience and ingenuity if waste is to be avoided and security maintained. The adaptation of existing apparatus to fresh requirements and the designing of novel implements to overcome new obstacles often call into play the inventive faculty, and gradually develop in the chemical practitioner a craftsmanship peculiar to his art. In this connection it is noteworthy that chemistry, although a branch of science, resembles the other branches, excepting mathematics, in retaining many characteristics of an art.

Nevertheless, for those who are mathematically inclined, chemistry offers many attractions. The extension of boundaries leads to conflict, and it has already been found that the borderlines of scientific study have a tendency to become interlaced. This has happened with chemistry and physics, and the interdependence of these two branches has become so complete that the study of physical chemistry has acquired the dignity of a separate branch, in which the exercise of mathematical science may find full play. Another application of the mathematical faculty may be made to the study of crystals, which abound in great variety among both organic and inorganic forms of matter.

Finally, it will be acknowledged by all those who have tasted the joys of chemical research and have contributed, in however modest a degree, to the sum of chemical facts, that independent investigation of the numerous problems which unfold themselves to the chemist offers great opportunities for the development of character. Veracity, perseverance, attention to detail, observation, judgment and patience are some of the qualities which the practice of chemistry should lead us to acquire, and however short of these virtues we may fall as human individuals, it would probably be admitted by every research chemist that the delights and disappointments of his work have assisted him philosophically to

"... meet with Triumph and Disaster,
And treat those two impostors just the same."

This acquirement is doubly valuable at the present moment, when for most of us life has become a silent conspiracy of broken hearts endeavouring to face a new world with whatever courage and cheerfulness can be mustered.

Hence it is justifiable to claim for chemistry that it offers innumerable exercises for the mind and is consequently an admirable training-agent for the young, besides being the source of continuous mental pleasure to the mature intelligence. Moreover, its application is not confined to the purely intellectual—as distinguished from the human—aspect of life. The development of chemical research in the direction of synthetic drugs has been remarkable in the production of numerous valuable remedies, and consequently the chemist has proved a useful ally to the physician and surgeon in the relief of human suffering. In following this line of work another branch of the main subject has incidentally been opened, namely, bio-chemistry, a province in which

biology and chemistry join hands to their mutual benefit. The cultivation of this field has brought out very clearly the fact that organic chemical processes underlie such important functions as animal digestion and assimilation of food, the curative treatment of disease by anti-toxins, and the various changes by which plants absorb carbonic acid from the air and minerals from the soil, thus enabling them to build up wood-cellulose, starch, sugar, and india-rubber; alkaloids such as nicotine, cocaine, and quinine; colouring-matters such as alizarin and indigo; poisons such as morphine and strychnine; spices such as pepper, mustard, vanilla and cinnamon; and finally, the long list of perfumes which delight the senses, such as camphor, rose, peppermint, jasmine, clove, lemon-grass, and violet.

It is one of the many regrettable features of human life that nothing approaching full advantage can be taken of the whole sum of human experience. Up to a certain point, however, the mistakes of one group of people can be used as danger-signals or sign-posts for a succeeding one, and although the war, when viewed as a calamity which has visited this generation, is an incalculable horror, its lessons and its discipline, if properly read and assimilated, may be turned to unceasing benefit by succeeding generations. It is the duty of those among us who may survive this visitation, or who, by the gallantry and self-sacrifice of our younger fellow-countrymen and allies, have been permitted to follow our respective callings in relative peace and comfort, to give our minds whole-heartedly to the task of so focussing these lessons that the benefit obtainable from them may be secured to our successors.

Searching, then, for a fundamental principle which would appear to explain our shortcomings in the past, we find that the great weakness of our national method has been, speaking broadly, neglect to study the inner qualities of the materials to be manipulated, both physical and psychological. The British engineering and textile industries have gained their foremost position amongst the great undertakings of the world by the outstanding skill of the workers engaged therein, supported by the daring and enterprise of the controlling heads. These qualifications, however admirable in themselves, will not alone enable us to maintain our position in the future. They must be fortified by an intimate knowledge of the chemical and metallurgical properties of the raw material, because it is only by such knowledge that crude products can be utilised with the finest and most enduring results, and their applications extended to ultimate possibilities. In making this claim I am not suggesting that everyone engaged in the textile industry should be a professional chemist or that engineers should be trained metallurgists. That is neither necessary nor desirable; but it is desirable that the practitioners of these two industries should have been provided with a bare outline of the respective branches of science underlying their occupation, and it is necessary that the directive heads should have access to highly-trained chemists and metallurgists for frequent consultation.

Reluctance to make use of college-trained men has been partly due to the discovery by some employers that a college training is incomplete and one-sided, but reflection should show that this is quite inevitable within the limits of time by which the average student is fettered. It is not possible to impart the kind of knowledge which can immediately be utilised to improve any but the worst works' processes, because an interval must elapse before a graduate can adjust his mind to the new environment. The factory differs fundamentally from the university in several aspects, important among which is the condition that whilst the chief aim of the university is to impart, classify and extend knowledge, often without much regard for expense, the principal purpose of the factory is to apply it as profitably as possible. Due allowance for this basic distinction has not been made by employers in the past, with a consequence that they have experienced disappointment and shown impatience with the human material provided by the colleges.

I do not pretend that the faults have lain on one side only. It has been claimed by manufacturers that the college graduate is too academic to be of practical value, and that professors are remote beings who float in an attenuated medium of their own hypotheses, ignoring the plain facts and requirements of industrial operations. In support of this contention illustrations could easily be quoted from public knowledge, but on the other hand it is not reasonable to expect men whose principal work lies in one field, namely, the extension and distribution of knowledge for its own sake, gracefully and authoritatively to exert themselves with equal success in surroundings novel and uncharted. Moreover, it should be remembered by business men that the professorial attitude, often regarded by

them as dictatorial and overbearing, arises largely from the nature of the professorial calling—namely, imparting knowledge to comparative beginners in their subject. A man whose chief activities are engaged in the daily transference of his own information to the less mature minds of the students in his class must be something of a superman if his mental attitude is not affected thereby, and this factor, associated with the habit of untrammelled and enthusiastic discussion of scientific problems with his fellow-investigators, may go far to explain that peculiar state of mind to which the business man takes exception, and which he sometimes labels intellectual arrogance.

As in solving all problems arising from human limitations, it is imagination which is needed, a readiness on both sides to make allowance for another standpoint; a determination, equally on both sides, to eliminate mere personal prejudices of outlook, combined with a joint resolution to concentrate in utilising the contribution which each side may be capable of making to the general advancement. To use a felicitous expression by Dr. George Pernet, there must be added to the *entente cordiale* an *entente cérébrale* between the practitioners of science and industry, which will enable them to penetrate each other's psychology, and in this process to cut the barbed wire as delicately as possible. This may sound like a counsel of perfection, as indeed it is, but it is not incapable of partial achievement provided both groups are deeply in earnest, realise the issues involved, and are not under any illusions as to the cost of failure.

Before this ideal can be fully attained, however, very radical alterations will need to be made in our system of education, which should be directed primarily towards giving every boy and girl an opportunity to reveal any natural gift which may lie hidden, and in the case of those who possess distinct mental aptitude, launching them on the road to develop it as fully as possible. It is probably true that genius will always come to light in spite of the most discouraging circumstances, but there is very little genius in the world compared with the huge aggregate of moderate capability which, like the mineral resources of an imperfectly explored country, has not yet been brought to the surface. To paraphrase a homely proverb, we must take care of the talents and the genius will take care of itself.

Had the doctrine of equal opportunity as between classics and science been pursued in the past, this generation of Englishmen would now be reaping two great benefits. In the first place the number of trained scientific workers in this country would have been much larger, and secondly, the general public, not actively engaged in the study of natural science, would have been much more accessible to the possibilities of scientific discovery. At present there is no perspective in such matters. A piquant illustration of the gulf between fact and fancy in the public mind was furnished last January by a prominent daily newspaper, which produced a mild sensation even in these sensational days by publishing a flamboyant and thrilling narrative, heavily headlined "GERMAN DYE SECRETS CAPTURED." From this it appeared that two enterprising gentlemen from the textile industry had commissioned a chemist to visit Switzerland and report on the value of "257 recipes" which had been spirited out of the Badische Anilin- und Soda-Fabrik. It was no "week in lovely Lucerne" for the chemist, who was represented as having been drugged, assaulted and thrown in the gutter; but the 257 recipes came through in safety and a Foreign Office bag. Newspaper interviews and correspondence flourished for some days afterwards—and very properly too, in view of the claim which had been put forward that "it will free the British textile industry and scores of other important industries from the bonds of Germany," whilst "when the war is over Great Britain will be in a position to compete equally with Germany in the matter of dyed goods in every market of the world."

I am willing to believe that the story was published in perfect good faith as a piece of honest journalistic enterprise, with a happy feeling that something really important had been accomplished and with a desire to hearten the public by good news; but it is really shocking, after the public attention which the subject has received, to encounter a picture of the dye-problem so illusory as the one mentioned. It suggests a revival of the poisonous heresy, very popular when war began, that Germany had stolen the dye-industry from this country, and that therefore we could steal it back. It evidently needs to be said again that Germany did not steal the dye industry from this country. Germany earned the dye industry, won it from Nature by hard work, indomitable patience, far-sighted employment of profits in fresh experiments, skilful organisation of resources, careful attention to the requirements of customers, scientific

control of manufacturing operations, ever-widening enlistment and encouragement of chemists, utilisation of by-products, ingenious application of engineering principles, and acquisition of cheap raw materials. If, after nearly four years of war, we cannot clear our minds of the pitiable nonsense which would suggest that forty years' exercise of these factors may be packed in a Foreign Office bag and stolen, we shall not only fail to establish the dye industry, but we shall richly deserve to fail. Incidentally, may I respectfully suggest to Lord Northcliffe that he should employ a trained chemist to review all impending articles on chemical subjects prior to publication in his otherwise enterprising journals?

This particular incident, whether grave or gay, according to the mood of the observer, illustrates very clearly one of the principal obstacles to an accurate valuation of their debt to organic chemistry by the public. Unlike astronomy, botany, geology and zoology, organic chemistry is extremely difficult to popularise—that is, to render interesting and intelligible to those without preliminary training in the subject. Consequently it happens that although every human being is a practical organic chemist, whose laboratory is occupied with complex experiments during every hour of the twenty-four, beginning with the matutinal porridge and bacon, the interest which is taken by the vast majority in these operations begins and ends with the satisfaction of hunger and the quenching of thirst. Even those who have the misfortune to suffer from indigestion do not reproach themselves for lack of skill in the practice of organic chemistry.

If we turn to the manufacturing side of the subject, a similar handicap in comparison with other crafts is presented. The visitor to a steel foundry is rightly thrilled at the sight of a ton of "pigs" dropping into the converter with as little disturbance as a lump of sugar falling into his after-dinner coffee, and he is very properly dazzled when many tons of limpid steel flow from the ladle as gently into the mould as a bottle of port into the decanter. The various processes of cotton-spinning and weaving delight the observer by their complexity and precision, whilst the growth of an automobile during an afternoon's curiosity engenders a warm feeling of respect and admiration for Mr. Ford and his fellow-craftsmen. All these experiences may be freely enjoyed without any preliminary knowledge of the properties of iron, the characteristics of cotton, or the laws of motion. Everything is different, however, in a chemical factory, inspection of which can be thoroughly appreciated only by those accustomed to practising similar operations in laboratory surroundings, when the principal enjoyment arises from the task of tracing the extraordinary liberties with laboratory practice which factory operation is compelled to take. The casual observer, even if he overcomes a natural distaste for fumes, live steam, and unfamiliar but suspicious odours, cannot unravel the maze of pipes and tubs and closed iron vessels which imprison the material undergoing change; the conversion of naphthalene into beta-naphthol, of aniline into para-nitraniline, or of nitrobenzene into benzidine, leaves him cold, because the finished product in each case is just as unfamiliar as the starting material, and is equally purposeless.

This blank in the training of the public, especially among those who are supposed to be the best trained, has played, and is still playing, an important part in retarding the development of a national dye industry. Not merely the incident of the "257 recipes," but others less ephemeral, indicate that even yet the crux of synthetic colour manufacture is not fully recognised in this country. Even yet it is not understood that the production of a colouring matter is but the culminating step in a long series of complex organic chemical operations directed towards converting the simple products of coal-tar distillation into the more complicated organic compounds known as "intermediates," so called because they are the stepping-stones between raw materials derived from coal-tar and synthetic dyes required by the dyer. If dye-making is ever to become established on a firm basis in this country, unceasing efforts must be devoted to manufacturing these intermediate products at the highest efficiency as to quality and cost, and to securing the necessary raw materials at the lowest possible rates. The achievement of this aim, which has been accomplished by German dye-makers during a period of forty years, and with indispensable assistance from a rapidly increasing body of trained chemists, will demand an outlay of capital much larger than has been ventured hitherto; moreover, the capital at first will appear to be unproductive, because it is only when the intermediate products for which it is laid out are actually manufactured that the ultimate object of dye-making can be accomplished. So long as we purchase "intermediates" in

Switzerland, the United States or elsewhere, we cannot claim to have established an independent British dye-making industry. Much of the uninformed criticism which has been levelled against British colour-makers by their fellow-countrymen arises from failure to understand and appreciate this cold fact. Bread cannot be made without flour, and it is just as reasonable to expect the weaver to produce fabrics without yarn as to demand colour from the colour-maker when capital for manufacturing the necessary intermediate products is withheld from him.

Nearly three years ago I ventured to prophesy that American progress in the field would be more rapid than our own, and a review of the development of this industry across the Atlantic has justified the forecast. The basis of their advance is to be found in the great scale on which essential intermediate products are being manufactured, and in the moral support which has been given by their Government in the shape of a tariff. It has not been found necessary for the United States Government to accord financial assistance to the dye-makers, because the promised defence against "dumping" and "all-line forcing" has appeared adequate to justify the venture of private capital, which has been amply forthcoming. It would appear to follow that in this country, if the State is not willing to give the fiscal guarantee, it must find the money.

[Since these words were written a declaration of Government policy has been made in the House of Commons by the President of the Board of Trade (May 15th, 1918). The following words are quoted from the Hansard report of his address:—

"In the first place, we are proposing, where a manufacturer of dyes will undertake the manufacture of special dyes, and where he is not in a position to secure the necessary money to provide for extensions to building and plant, to make a loan at a fixed rate of interest, in no case being less than 5 per cent. It is also proposed to do as is done by the Ministry of Munitions in many thousands of cases. Where extensions of plant and buildings are necessary immediately, and where there is difficulty owing to the excessive costs of making these extensions, the Government will make some provision to meet the cost of these extensions, so that they may be immediately dealt with, and thus afford the additional facility that is required for the manufacture of these special dyes. It is also proposed to make certain grants in respect of research work. Those who have a knowledge of this industry realise the enormous amount of research work associated with the manufacture itself. There is a further proposal, and that is that, in order to safeguard this particular industry against the great efforts which these great German dye-making firms are certain to make after the war to destroy all we have accomplished through the war, and to make this industry again subservient to Germany, we will adopt a course, which I believe I am right in saying was carefully considered by a Cabinet Committee of the last Government, and recommended to and approved by the Government of that day, and which has since been approved by the present Government. It is that importation of all foreign dyestuffs shall be controlled by a system of licences for a period of not less that ten years after the war. . . . We have been in consultation with representatives of dye-makers and dye-users, and they, I am glad to say, are in agreement on this matter. I have agreed with them that a licensing authority shall be established by the Board of Trade, which will have a free hand in deciding as to the grant of licences. That Committee is to be composed of an equal number of representatives of dye-makers and of dye-users, in each instance nominated by these interests. There will be an independent Chairman of this Board, a man of good business standing, appointed by the President of the Board of Trade."

For all those who have laboured in bringing to the attention of their fellow-countrymen the vital importance of chemical study, there are hope and inspiration to be derived from this pronouncement.]

Money, however plentiful, and State encouragement, however wise and cordial, will not alone suffice for the purpose in hand.

"The Moving Finger writes; and having writ,
Moves on: nor all your piety nor wit
Shall lure it back to cancel half a line,
Nor all your tears wash out a word of it."

For those who have eyes to see and intelligence to understand, the Moving Finger has written more clearly on the walls of this industry than elsewhere. The boundary-line between German success and British failure in the fine chemical industry stands defined as clean and sharp as if cut out of metal. Briefly stated, it lies in the allocation of profits. A farmer who reaps a field of corn and garners the product can either sell it and pocket the proceeds, or he can sell enough to pay the rent of the field, the labour which has been expended upon it, and a modest return on his capital, utilising the remainder to produce next year's crop. Adopting the latter course he has a still larger crop, whilst the former course gives him none. The German chemical farmers have chosen the far-sighted practice, each year devoting more and more seed, in the shape of constantly widening

chemical studies, to sowing new fields. On the other hand, many of our chemical farmers engaged in coal-tar colour manufacture have taken the short view, withdrawing such handsome personal profits as, had they been returned to the industry and sown in the conduct of scientific experiments, would have produced the abundant harvest which has been reaped by Germany.

On September 9th, 1912, Carl Duisberg, managing director of the Farbenfabrik vormals Friedrich Bayer, stood surrounded by the splendid fruits of this policy, addressing the Eighth International Congress of Applied Chemistry, and I can recall, quite vividly, my own sensations on that occasion. They were the delight and admiration of a chemist in the achievements of chemists, shadowed by the shame and regret of an Englishman in contemplating the slender part played by his own country in the dazzling developments of chemical investigation. A multitude of German chemical products covered the table and overflowed to the platform, whilst the address itself was a florid eulogium of German chemical enterprise. The following words, however, call for special attention, indicating as they do the mainspring of this vast mechanism: "In the chemical works of Germany pure chemical science receives its due. In every branch of inorganic, organic and physiological-biological chemistry we are working with an army of scientifically trained men."

Six years earlier, on the occasion of the Perkin Jubilee, the same captain of German chemical industry was analysing the causes of German predominance in coal-tar colour and drug manufacture, and said: "Although the Englishman is in general practical, he is wanting in that particular quality for which we Germans are remarkable—*i.e.* not perseverance, but patience and the power of waiting for success. For all that the Englishmen does he expects soon to be compensated in hard cash. In no field of technical work must one toil with such patience, and even with the eventual relinquishment of material recuperation, as in the coal-tar colour industry. It does not suffice merely to plough and dig up the soil in the most ardent manner, it does not suffice to impart to it mental and intellectual manure of all kinds—*i.e.* nitrogen in the shape of skilled technical chemists, and phosphorus in the form of distinguished inventors and scientific chemists, for both of these are purchasable and have often been tried; but it requires above all a singular ability to wait and bide things coming, combined with endless patience and trouble until the ground is finally mature and capable of developing new kinds and species. We Germans possess in a special degree this quality of working and waiting at the same time, and of taking pleasure in scientific results without technical success."

These words were uttered in a moment of expansion by the man who, perhaps better than any other, is qualified to give an opinion, and than whom no one could express it more clearly and forcefully. Entering the Elberfeld Farbenfabrik in 1884 as an assistant chemist at a salary of £90 per annum, it is to his unbounded energy and unquenchable optimism, guided and controlled by deep scientific insight and shrewd commercial faculty, that the establishment and success of the Leverkusen factory are principally due. In presenting this picture of ourselves as others see us, it may be of interest simultaneously to present a portrait of the artist by the President of the Hansa League in 1909, when he addressed Carl Duisberg, then completing twenty-five years' service with the company, in the following terms:—

"That your industrial success and activity have been constructed on scientific foundations, extended by scientific discoveries, and by scientific methods elevated to a high altitude, is shown by your title of Professor conferred by the State and by the honorary degrees of Doctor which you hold in two faculties. This alone, however, is insufficient to explain the powerful, even dominant influence which you exert upon those with whom you come in contact, be they colleagues or subordinates. It is more a property which you possess in addition to warm-heartedness, in addition to that wide range of vision enabling you to recognise the demands of the future equally with those of to-day, a property which marks you out and brings you closer to our German hearts. For you possess that true German idealism which happily has not yet deserted our nation of poets and thinkers, although we be compelled by the stern struggle for existence to place economic interests in the foreground. Withstanding the corrosion of industrial rivalries, you have proved in all your being and your work that those elements which can be neither seen, nor weighed, nor grasped are nevertheless the greatest, the best, the most indispensable in our lives, namely, ideals. Your ideal has been the honour, progress and triumph of your undertaking, the fortune and advancement of those who stand under your command, and not least, the increase of power, of reputation and of dignity to our Fatherland."

This particular selection is made from the 120-page book of similar utterances on that occasion because it appears to reveal, in clear

and striking language, the *Leitmotiv* and driving principle of the German industrial aristocracy. The combined appeal to legitimate pride, to chastened self-interest, and to the highest patriotism conveys a lesson which no Briton can afford to ignore.

Moreover, the creed goes far to explain, although it does not condone, the exasperation and resentment of Germany at the relative pre-war position of the two countries, largely instigating the crime which that country has committed against civilisation. I can imagine that the German argument would be somewhat as follows:—We find ourselves an association of nearly seventy million people, not yet fifty years old as a nation. With few gifts of Nature and fewer geographical advantages we have, by our industry and co-operative determination, adapted the teachings of modern science to every branch of commerce. In doing so we have not neglected the physical and mental well-being of the operatives concerned in these developments, and whose livelihood depends on their success. Nor have we ignored the fount by which this marvellous growth has been irrigated, namely, abstract knowledge and investigation, for our numerous universities open their gates to the youth of every class, and our teachers are honoured in the land. Engaged in these arts of peace, and profiting enormously by their material results, we have nevertheless continued to make such sacrifices of time, convenience and money as are necessary to military preparation, and have simultaneously gained a position excelled only by your own on that element which is historically and geographically yours, and correspondingly alien to our history and geography—the ocean. Meanwhile, what is your record? You are an ancient race, which has now stood for centuries in the forefront of the battle for liberty and progress. Your pioneering predecessors, assisted by the blunders of your adversaries, have lavished upon you priceless territorial jewels. All these you have accepted with a sublime disregard for the duty which you owe to Destiny, for whilst *noblesse oblige* may be your motto as individuals, it seldom appears to inspire your politics. You were the first to reap the harvest of the industrial revolution, yet for half a century your factory system was a disgrace to civilisation. Your inventors and discoverers have lingered in oblivion unless they happened upon some device by which their researches could be turned immediately into gold. Abstract knowledge meets with your polite but callous indifference. Your rulers have been drawn systematically from those in whom this indifference is the most profound, and whilst displaying high qualities of honourable statesmanship, they have studiously ignored the vital and revolutionary forces which had reached a crescendo of world-activity in the closing years of the nineteenth century. Your people, wholesome and cleanly in their family relationships, have nevertheless shrunk from the one sacrifice which, in ultimate issues, offers the only safeguard for their homes; they have preferred to devote their leisure to sport and amusement, which they more often pay to witness than practise in person. Instead of being directed towards those great problems of social amelioration, racial harmony and the co-ordination of resources which your splendid empire has imposed upon you, your political energies appear to be largely dissipated in pitiful squabbles between the "ins" and the "outs." With your record of neglect, you then have the effrontery to scowl at our record of achievement, and to grudge us a place in the sun. *Gott strafe England!*

Naturally I do not subscribe to this indictment, but I believe it to be the German standpoint, and in that sense it merits attention.

The conclusion of the matter appears to be roughly this. It takes all sorts to make a world, and the world, as we find it, contains Germans. Even when justice has finally triumphed, however many Germans may be destroyed in the process, there will still survive more millions than the inhabitants of this country. For us it is necessary to face the facts which, upon our easy-going people, have dawned somewhat slowly. At the beginning we were willing to believe that it was the Kaiser's war as distinct from the German people's war. The world has now learned our mistake. Lichnowsky, among others, has proved that in one sense it was the Kaiser's war, but in doing so has proved that it is the war of the German people also, because, with convincing evidence before them, they have not disowned the war, and other circumstances, too many and too disgusting to enumerate here, have established the proof.

How does this affect chemistry? It affects chemistry and modern science generally, because the scientific men of this country require to watch closely their claim to scientific honesty. We must guard ourselves against the danger of allowing admiration for German scientific achievements to blind our eyes to German

popular brutalities. Let us closely study the achievements and use all our powers to surpass them, but let us never, so long as we claim to be human beings, forget or forgive the brutalities. Let us remember that if we aim at being scientific men, as distinct from scientific machines, we must be men first and scientific afterwards; men with human hearts, which can be torn by the ruthless destruction of children, by the murder and worse than murder of women, by the neglect and starvation of helpless prisoners, and by the public spitting in their faces. Wretches who perpetrate such abominations, or who condone them, are not fit for association hereafter with decent men, and human facts of life being more important than chemical facts, it is grossly unscientific to ignore them. The abominations must be brought into account, just as much as the synthesis of indigo, salvarsan, indanthrene and nitric acid from the atmosphere, and no man who lays a claim, however strong, to be regarded as a scientific man can pretend for one moment that they do not vastly preponderate.

DISCUSSION.

The Chairman (Sir William A. Tilden, D.Sc., LL.D., F.R.S.), in opening the discussion, said no one could have listened to the paper without feeling almost personally the reproaches which the author had justifiably launched against this country for its indifference and torpidity in the past. He did not think any English man or woman could refuse to accept the statements made towards the end of the paper, and he sincerely hoped that all of them, especially the young men who might find their way into industries in the future, would take to heart the lessons so clearly set forth in the body of the paper.

Dr. J. C. Cain wished to call attention to the difference in the organisation of scientific manufactories in England and Germany, that difference consisting chiefly in the composition of the boards of directors. Before the war such works in England were not as a rule directed by scientifically trained men, but by what were generally known as business men, the directors meeting perhaps once a month to ascertain how the work was going on and to learn what dividends were going to be paid. The boards of directors in Germany, however, actually directed. They were composed of men who had prominent positions in the works, such as the chief chemists and the chief engineers. The business men and capitalists were also represented, and every man on the board knew something about the business which he helped to direct. In connection with the author's concluding remarks, with which he entirely agreed, it was almost impossible to attend a meeting of chemists in London without being irritated and annoyed by the presence of Germans, and he thought those Germans should be requested not to attend chemical meetings during the war. The paper read at the present meeting would probably be fully reported in German scientific journals.

The Secretary (Mr. G. K. Menzies) said that when the present meeting was first arranged he was very anxious that the author should not have to preach only to the converted, and he made such efforts as he could to secure the attendance of a number of manufacturers. He was sorry to say that he had not been very successful, partly because manufacturers were very busy at the present time and partly because they seemed to be somewhat shy of attending such meetings, where they were afraid remarks not altogether complimentary would be made about them. Amongst others he wrote to Sir George Watson, the Chairman of the Maypole Dairy Company, who replied that he would have been very glad to come had he not been out of town. In January last Sir George Watson read an admirable paper before the Society, in the course of which he made several remarks which were very relevant to the present paper. He said: "At Maypole's refining mills and margarine works we consider the laboratories to be one of the most important parts of the organisation, and no expense for research is spared there which will help towards future progress. I fear that in the past some British manufacturers have not attached so much importance to the expert and scientific assistance of their chemists and chemical engineers as their Continental competitors." In replying to the discussion, Sir George Watson also said: "With reference to manufacturers employing chemists, those chemists should be given seats on the board of directors, as is the case in the Maypole Company, so that they can become fully acquainted with all the details of the business." On his own behalf he would like to say how very much he had appreciated Dr. Forster's paper. He was, unfortunately, not qualified to criticise it on the technical side, but as a literary performance he thought it admirable.

The Chairman, in proposing a vote of thanks to the author, said he had listened to the paper with the very greatest interest and satisfaction. The British public were still in a state of torpor, more particularly with regard to such industries as those mentioned in the paper, and he hoped the author would take every possible opportunity to stir them up to action. One could not complain because the ordinary British citizen did not know anything about organic chemistry, and probably did not even understand what the expression meant, but what he was continually complaining about was the fundamental and profound ignorance of every kind of science which was manifested by the British public. Not very long ago there were dozens of colonels and countesses and reverend

gentlemen who were prepared to testify publicly that by adding a teaspoonful of a certain powder to a ton of coals the heating power of the coal could be increased 50 per cent. That of itself was sufficient to show the ignorance of the British people with regard to science. Those people were educated people, who would be offended if anyone said they were grossly ignorant, and yet they did not know one of the fundamental principles of physical science. One had only to look at the advertisements in the daily papers to see how gullible the British public was. The words "radium" and "argon" were applied in all kinds of different ways, and the people who responded to the advertisements had not the least idea what radium and argon were. The cure for that widespread ignorance was, as the author had stated, a reform of our educational system. The public schools had been saying for the last forty years that they taught science to all their boys and girls, but that was not true. Many of those institutions had excellent laboratories and competent masters and mistresses, but when they said they taught science, it only meant that a portion of the school devoted two hours a week to the subject, while they devoted twenty-five hours to other subjects. They did not give science a reasonable and fair proportion of time and attention. "Science" implied some knowledge of the whole of the physical universe in which we found ourselves. How many people knew anything about why the sun rose in the east and set in the west, or why the days were longer in summer than they were in winter? How many people could tell what was the nature of the soil they walked upon daily? On the previous day he was talking to a soldier, and mentioned that he lived on the edge of the London clay, and the soldier did not know what that meant—he did not know what clay was. Again, how many people knew the chief divisions of the animal kingdom, or could recognise the botanical relationships of the commonest plants? Yet those people would be offended if they were called uneducated. He complained particularly that not only was that ignorance prevalent generally throughout the community, but that it extended and became, in some respects, intensified as one went from the bottom of society to the top. How many men in the House of Commons could claim to have had an education in which science occupied a fair position? He had been trying to think whether there was anyone in the Government offices in Whitehall who was qualified to deal with scientific questions, and he could only think of one—an eminent mathematician—who was by predilection occupied chiefly in the study of ancient Greek geometry. That was not a state of affairs with which we ought to be satisfied. He was firmly convinced that the present Government was doing its best in the conduct of the war, and he did not believe in perpetually worrying the Government about other matters, but if the nation was to continue in a position of safety and reasonable prosperity, such things would have to be considered when the war was over.

The resolution was carried unanimously.

DR. M. O. FORSTER, in reply, said that his only serious connection with industry dated from the beginning of the war, so that the Chairman's criticisms clearly could not apply to him. He would like the meeting to return a hearty vote of thanks to Sir William Tilden for occupying the chair. He had been associated with Sir William for the last twenty-five years, and it had been a very great pleasure to him personally that Sir William should have presided on the present occasion.

The meeting then terminated.

THE ECONOMIC SITUATION IN INDIA.

A section of the monumental report of Mr. Montagu and Lord Chelmsford on Indian Constitutional Reforms is devoted to "Industries and Tariffs." In the course of their investigations the criticism was forced on the Secretary of State and the Viceroy that economic factors enter largely into the political situation, and they say they feel bound so far to exceed the limit of strictly constitutional discussions as to take note of these also.

The poverty of the people raises the question whether the general level of well-being could not be materially elevated by the development of industries; the lack of outlet for educated youth has contributed not a little to political unrest in Bengal, and discontent has been aroused by India being so largely dependent on foreign countries for manufactured goods. The fact that India's foreign trade was largely with the United Kingdom gave rise to a suspicion that her industrial backwardness was positively encouraged in the interests of British manufactures, and the maintenance of the Cotton Excise Duty is widely accepted as proof of such a purpose.

Under the Company commercial development was, of course, a matter of business. *Laissez faire* doctrines and fear of State competition with private enterprise affected the later attitude of the Government. As the desirability of industrial expansion became clearer, the *Raj* fully shared the desire of Indian leaders to secure the economic advantages that would follow the local manufacture of raw products. English theories as to the limits of the State's activities are inapplicable to India, and if the resources of the country are to be developed the Government must take action. The attempt to boycott British goods, encouraged or countenanced by the advanced politicians as a means of putting pressure on manufacturing opinion in Britain in favour of the annulment of the partition of Bengal, was ineffective, and certain indigenous enterprises which sprang from the *swadeshi*

movement failed through inability to apply some degree of technical knowledge under commercial conditions. The people have now recognised that they cannot carry out their own programme without the help and guidance of Government, and they confine themselves for the most part to pressing their claims for State assistance and tariff discrimination against foreign imports. On the outbreak of war they welcomed the prohibition of imports from enemy countries as affording India an opportunity of replacing foreign articles by her own products.

"After the war the need for industrial development will be all the greater unless India is to become a mere dumping-ground for the manufactures of foreign nations, which will then be competing all the more keenly for the markets on which their political strength so perceptibly depends. India will certainly consider herself entitled to claim all the help that her Government can give her to enable her to take her place as a manufacturing country; and, unless the claim is admitted, it will surely turn into an insistent request for a tariff which will penalise imported articles without respect of origin. On all grounds a forward policy in industrial development is urgently called for, not merely to give India economic stability, but in order to satisfy the aspirations of her people, who desire to see her stand before the world as a well-poised, up-to-date country; in order to provide an outlet for the energies of her young men who are otherwise drawn exclusively to Government service or a few overstocked professions; in order that money now lying unproductive may be applied to the benefit of the whole community; and in order that the too speculative and literary tendencies of Indian thought may be bent to more practical ends, and the people may be better qualified to shoulder the new responsibilities which the new constitution will lay upon them."

On military as well as economic grounds Imperial interests demand that the natural resources of India should be better utilised. The possibility of sea communications being temporarily interrupted forces us to rely on India as an ordnance base for protective operations in Eastern theatres of war.

"We are agreed, therefore, that there must be a definite change of view; and that the Government must admit and shoulder its responsibility for furthering the industrial development of the country. The difficulties by this time are well known. In the past, and partly as a result of recent *swadeshi* experiences, India's capital has not generally been readily available; among some communities, at least, there is apparent distaste for practical training, and a comparative weakness of mutual trust; skilled labour is lacking, and although labour is plentiful, education is needed to inculcate a higher standard of living and so to secure a continuous supply; there is a dearth of technical institutions; there is also a want of practical information about the commercial potentialities of India's war products. Though these are serious difficulties, they are not insuperable; but they will be overcome only if the State comes forward boldly as guide and helper. On the other hand there are good grounds for hope. India has great natural resources, mineral and vegetable. She has furnished supplies of manganese, tungsten, mica, jute, copra, lac, etc., for use in the war. She has abundant coal, even if its geographical distribution is uneven; she has also in her large rivers ample means of creating water-power. There is good reason for believing that she will greatly increase her output of oil. Her forest wealth is immense, and much of it only awaits the introduction of modern means of transport, a bolder investment of capital, and the employment of extra staff; while the patient and laborious work of conservation that has been steadily proceeding, joined with modern scientific methods of improving supplies and increasing output, will yield a rich harvest in future. We have been assured that Indian capital will be forthcoming once it is realised that it can be invested with security and profit in India; a purpose that will be furthered by the provision of increased facilities for banking and credit. Labour, though abundant, is handicapped by still pursuing uneconomical methods, and its output would be greatly increased by the extended use of machinery. We have no doubt that there is an immense scope for the application of scientific methods. Conditions are ripe for the development of new and for the revival of old industries on European lines; and the real enthusiasm for industries, which is not confined to the ambitions of a few individuals, but rests on the general desire to see Indian capital and labour applied jointly to the good of the country, seems to us of the happiest augury."

Many Indians urge that the Government should make up by financial subsidies the ground which has been lost by what they regard as State indifference. The extent and form of State assistance will be questions to be determined by the reformed Governments of the future, with the advice of the Industrial Commission before them, and with due reference to Imperial interests. But if the speculative element in Government activities is to be minimised, there must be a marked expansion of the technical services of the country. The Industrial Commission has not yet submitted its report; but it is understood that it is likely to lay stress on a substantial increase in the scientific and technical services of the country and their organisation under a separate department of the Government of India.

With regard to fiscal policy, the Secretary of State and the Viceroy have "no immediate proposals to make," but for the information of His Majesty's Government they put forward a succinct and impartial statement of the views of educated Indians upon the subject. The authors of the report believe that the theoretical free trader "hardly exists in India at present."

In a separate paragraph on the "The Non-Official Community" they observe, *inter alia*—

"When complaints are rife that European commercial interests are selfish and drain the country of wealth which it ought to retain, it is well to remind ourselves how much of India's material prosperity is due to European commerce."

NOTES ON BOOKS.

TIDAL LANDS: A STUDY OF SHORE PROBLEMS. By Alfred E. Carey, M.Inst.C.E., and F. W. Oliver, F.R.S. London: Blackie & Son, Ltd. 12*s*. 6*d*. net.

This book deals with a number of the problems connected with the maintenance and control of coastal and riparian lands, and especially the changes which may be effected by vegetation. The subject is one of great importance and interest to engineers, to landowners, and to all concerned with the question of coast erosion.

The phenomena connected with tides, wind effects, currents, and river velocities, are discussed in the first two chapters, and then, after a section on the foreshore, we come to the portion which treats of vegetation. This is very full and of particular value. The manner in which sand dunes may be fixed by the growth of various kinds of marram grasses is described in detail; diagrams are given to show the effects of planting, and some excellent photographs illustrate the results obtained. A good deal of attention is naturally devoted to Holland, the very existence of which depends to a large extent on the maintenance of its sand dunes.

Shingle beaches are next discussed, and the ways in which they may be protected and utilised by planting. The reclamation of tidal lands is also treated. A special chapter is devoted to "Blakeney Point, Norfolk, from an Engineering Point of View," which is selected as a suitable demonstration area on the coast; and the work concludes with two chapters on State and local control and complementary problems.

The book is written throughout in a scholarly style; it contains a great deal that is original; and the scientific portions show evidence of careful research and observation.

GENERAL NOTES.

BRITISH GUIANA AND THE PROBLEM OF ITS DEVELOPMENT.—In the House of Commons on July 4th Colonel C. E. Yate asked the Secretary of State for the Colonies whether his attention had been called to the lecture lately delivered at the Royal Society of Arts by Sir Walter Egerton on the subject of British Guiana; and what steps would be taken to carry into effect the nine different reforms advocated by that officer? The Under-Secretary of State for the Colonies (Mr. Hewins) replied as follows: "The answer to the first part of the question is in the affirmative. Generally speaking, the measures advocated by Sir Walter Egerton have received, and are receiving, a great deal of attention. Some of them are being carried out; but others are of such a nature that they cannot be dealt with during the war, and one involves political changes on which I am not prepared to express an opinion. As regards the scheme for a railway to the interior, upon which Sir Walter Egerton lays such special stress, a practical step is already being taken by clearing a cattle track along a line which coincides with one of the proposed tracks.

WATER-POWER RESOURCES COMMITTEES.—A representative committee, appointed by the Board of Trade, is examining the water-power resources of the United Kingdom, and the extent to which they can be made available for industrial purposes. The chairman is Sir John F. C. Snell, M.Inst.C.E., and the secretary Mr. R. T. G. French, 10, Princes Street, Westminster, London, S.W. 1. Mr. E. S. Montagu recently stated in the House of Commons that the Government of India propose to constitute a small committee of electrical, mechanical, and irrigation experts to visit the different provinces, and, after conference with the local officers, to examine promising sites and to report whether a detailed survey is worth undertaking.

PRODUCTION OF SUGAR FROM THE PALM.—In a note which appeared recently in the *Journal*,* reference was made to a new industry, viz. the manufacture at Loano of cattle food from various waste substances, the sugar used being obtained from a species of wild date palm, which grows abundantly on the Ligurian coast, as well as on the French Riviera. The manufacture of sugar from the palm tree is no novelty to our Indian readers, although unknown hitherto on the shores of the Mediterranean. In Southern India, large quantities of sugar are obtained from the wild date palm by the natives. The trees are tapped by making an incision in the bark, just below the flowering stem. The sap which flows from this cut is collected in small earthenware pots or jars, holding about half a pint each. These pots are collected morning and evening. The liquid so obtained is boiled down, leaving a kind of coarse dark-brown sugar. The pots must be kept scrupulously clean and whitewashed, in order to prevent fermentation. This sugar is used chiefly by the natives, and is regularly sold in the bazaars. It is known by the native name of "Chakara," pronounced "Jaggery" by Europeans.

JOURNAL
OF THE
ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

All communications respecting Advertisements should be addressed to the ADVERTISEMENT MANAGER, 97, GRESHAM STREET, E.C. 2.

Journal of the Royal Society of Arts.

No. 3,426. VOL. LXVI.

FRIDAY, JULY 19, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

PRESENTATION OF THE SOCIETY'S ALBERT MEDAL TO SIR RICHARD GLAZEBROOK.

The Council of the Royal Society of Arts attended at Clarence House on Thursday, the 18th inst., when His Royal Highness the Duke of Connaught and Strathearn, K.G., President of the Society, presented its Albert Medal to Sir Richard Tetley Glazebrook, C.B., Sc.D., F.R.S., "for his services in the application of science to the industries of peace and war, by his work as Director of the National Physical Laboratory since 1899, and as Chairman of the Advisory Committee for Aeronautics."

The members of the Council present were: Mr. Alan A. Campbell Swinton, F.R.S. (Chairman), Sir Charles Carrick Allom, Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., Lord Blyth, Major Percy A. MacMahon, R.A., LL.D., Sc.D., F.R.S., Dr. William Henry Maw, Major-General Sir Desmond D. T. O'Callaghan, R.A., K.C.V.O., Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S., Sir Francis Taylor Piggott, LL.M., Sir Boverton Redwood, Bt., D.Sc., F.R.S.E., Lord Sanderson, G.C.B., K.C.M.G., Mr. John Slater, F.R.I.B.A., Mr. James Swinburne, F.R.S., Mr. Carmichael Thomas, Sir Henry Trueman Wood, with Mr. G. K. Menzies, Secretary.

EXAMINATIONS.

The results of the Stage III. (Advanced) examinations, held from May 6th–16th last, have now been sent to the centres concerned. It is hoped to issue the results of the Stage II. (Intermediate) examinations at the end of this month, and those of the Elementary Stage about the middle of August.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, June 20th, 1918; The Right Hon. E. S. Montagu, M.P., Secretary of State for India, in the chair.

The Chairman, in opening the meeting, said he much appreciated the invitation which the Royal Society of Arts had extended to him to take the chair on that occasion. He was well aware of the valuable Imperial work which the Society performed in bringing important questions, such as those connected with India, before the public. He regarded it as a matter of great importance that the public should be well informed on Indian questions and the development of India, which had been so rapid in recent years. It was only by constant discussions on Indian questions that it was possible to give those who unfortunately had no personal connection with the country an idea of the rapid progress there was in every direction. That progress had been much fostered by the war, which had given India increasing opportunities of showing her loyalty to the Crown and of co-operating with other parts of the Empire in the great task in which they were engaged. It was because he appreciated the work that the Society did to enlighten the public on those and kindred topics that he was particularly pleased to be able to accept their invitation to preside at the present meeting, when Sir Dinshaw Wacha's paper was to be read. Unfortunately Sir Dinshaw was in India, and therefore could not attend to read his paper in person. To those who had lived in Bombay Sir Dinshaw needed no introduction; his name had for long been a household word in that city, and there was no one to whom it was not very thoroughly known. Educated in Bombay, and finishing his education at the Elphinstone College, he at once associated himself with other graduates who issued from that institution in the early sixties. Prominent among them was the late Sir Phirozshah Mehta, between whom and Sir Dinshaw Wacha there had been both a lifelong friendship and a lifelong collaboration in municipal and political endeavour. Together they wielded great influence in the Municipal Corporation of the City of Bombay, which,

under their guiding influence, had earned a record second to that of no other city in India. Equally together they fostered for many years the growing political aspirations of their fellow citizens, and, working always on constitutional lines, they did much to advance political ideas, primarily among the people of Bombay, but also throughout India generally.

The paper read was—

INDIAN COTTON AND THE COTTON-MILL INDUSTRY.

By The Hon. Sir Dinshaw E. Wacha,
Chairman of the Bombay Millowners' Association.

It is scarcely necessary to observe at the outset that cotton and cotton manufactures occupy a foremost place in point of value among the few principal articles of merchandise which India annually exports to foreign countries. Her total exports of all kinds of commodities during the quinquennium which ended on March 31st, 1914, averaged £146·30 million per annum. Of these the six articles specified below alone amounted to £123·30 million:—

	Million £
1. Grain, chiefly rice and wheat	30·50
2. Cotton and cotton manufactures	29·79
3. Jute and jute manufactures	28·30
4. Seeds	16·24
5. Hides and skins	9·72
6. Tea	8·71

As far as raw cotton exports are concerned, it may be said that their value averaged £22·18 million during the quinquennial period just referred to, while the amount recorded on March 31st, 1917, was £22·78 million, though the quantity of the raw material itself had necessarily undergone diminution and was comparatively less than that exported on March 31st, 1914. India, it is superfluous to say, is not the only country which extensively grows cotton. Firstly, there are the United States of America, and, secondly, Egypt. These three countries supply by far the largest quantity of cotton grown in various parts of the world. Thus Indian cotton is, for all commercial purposes, in no way a "monopoly" article of merchandise as jute is; the world which consumes jute almost wholly depends on India.

Antiquity of Indian Cotton.

From the earliest historical times cotton and cotton fabrics have been well known. The ancients were well aware of these, as related by Greek and Roman geographers and travellers. The Old Testament also bears testimony to the fact. But it is needless to refer to foreign historians when there is ample evidence in the indigenous literature of the country of the cultivation of the cotton-plant—"the white wool growing on the tree" of Herodotus—and also of the fabrics made therefrom. Cotton thread and cotton cloth have been known in India from the remotest antiquity. It is related of the Hindu gods and goddesses of the Vedic period how they wore woven garments. The Aryans who invaded the country later found the industry of cotton-spinning and weaving well established. In the Indian epics of the *Mahabharata* and the *Ramayana* mention is made of cotton goods of divers designs. There is no doubt that the fine muslins of Eastern Bengal, such as "The Evening Dew" or "Running Water," were made anterior to the invasion of the Aryans. In his excellent book on the "Cotton Plant," Mr. R. B. Handy, of the United States Agricultural Department, mentions that cotton thread and cloth were referred to in the laws of the great Hindu lawgiver, Manu (800 B.C.). Professor Sayce, in his Hibbert Lectures, expresses his belief that cottons were exported to the head of the Persian Gulf in the fourth millennium B.C. Again, it is related by the great Greek historian that the Indian contingent who accompanied the army of Xerxes in his invasion of Greece (480 B.C.) were seen in white cloth, which could not be aught else than cotton. According to the *Imperial Gazetteer*, Asoka is said to have sent missionaries to Pratisthana of the Sanskrit books, in the Godavery district, and inscriptions of the second century before Christ in the Petalkhara caves refer to the kings and merchants of Pratisthana. Further evidence is to be found of the growth of cotton in the first century of the Christian era in Surashthra, the ancient Syrestrene, which is described as a fertile country, yielding wheat and rice, sesamum oil and ghee, cotton, cotton cloths and silks of a variety of designs. Pratisthana was an *entrepôt* of the cotton industry. The Sanskrit word for cotton is Karpāsa, which is the same generic word as Kapās, commonly used all over India. The Hebrews had a similar word, "Carpas," the Greeks "Karpasos," and the Romans "Carbasus."

It was the Arabs who called it "Kutan," whence the English word cotton. Both Pliny and Pollux state that cotton was grown in the island of Tylos, in the Persian Gulf, and, according to Theophrastus, in Arabia also. Again, the author of the "Periplus of the Erythrean Sea" confirms this by mentioning it as an article of export from Ommana (Oman).

Even to-day there is a port in the Red Sea, near Hodeida, called Comfidda, whence cotton is exported.

Old Indian Trade Routes and Traders.

A few words may be said here as to the routes by which Indian trade was carried on. Modern Cambay and Broach (the Bhrigukacha of Sanskrit and Barygaza of the Romans) were the two centres where, of old, Indian merchandise for export to Arabia, Egypt, and distant Rome, gravitated from the north, the east and the south. Thence the goods were transported in native craft, almost identical with the buglas, prows, etc., of our days, to the Persian Gulf and Aden, as far as Mocha (Mūsā). There the products of Egypt and Arabia, and also treasure from Rome, were exchanged by Roman, Greek, Egyptian and Arabian merchants. Mocha was the great *entrepôt* of ancient commerce in the Red Sea between India and the West. But there were land routes also. Considerable trade was carried on by land conveyances and river navigation, especially from the Punjab as far as the Caspian Sea. Thence Indian goods were transported to Constantinople. Trade was maintained at Palmyra through the Euphrates valley, which is once more coming into importance by reason of our present occupation of Mesopotamia. We may pass over the first thousand years after Christ till the era of the Crusaders. After their retirement from Jerusalem, say, in 1187, St. Jean d'Acre, a seaport of Palestine, became their chief residence and the principal emporium of the Mediterranean, where the products of the East and the West were exchanged. Merchants from Venice, Genoa, and other commercial cities of Italy, were the great intermediaries. Constantinople thus became a great mart for all Indian goods, particularly the fine cotton fabrics. Marco Polo may be said to be the great pioneer who, having travelled to the Near and Middle East in the latter part of the thirteenth century, exhorted the European communities in south-eastern Europe to trade with the East Indies. The Venetians were the foremost to monopolise the Indo-Egyptian trade. They enjoyed this commercial monopoly till the fifteenth century, when Genoese power and commerce declined. Malacca, in the East. became also a great emporium, and the cities of Calicut and Cambay were particularly flourishing. Bengal cloths, especially the world-famous Dacca muslins, were in great request. Goods were carried from Cambay to the head of the Persian Gulf, and thence to Basra. From Basra, by navigation of the river and by caravans, they were conveyed to Aleppo, Damascus and Beyrout. There the Genoese, the Venetians and the Catalonians exchanged products and magnificently flourished. The other route was from Aden to Cairo. Lastly, other Indian merchandise was entirely carried overland by way of Kashgar and Balkh to the Caspian Sea, and even as far as the Baltic ports.

European Venturers of the Fifteenth Century.

The history of Portuguese and Dutch commerce with India may be passed over. Suffice to say that the two nations were the forerunners of the East India Company. The venturesome enterprise of the merchants of the days of good Queen Elizabeth was no doubt first stimulated by the argosies which the daring traders of the two nations took away from this country. These English merchants first established their factories at Surat, which, after the decline of Broach, was the great highway of commerce between the East and the West till Bombay eventually outstripped her and secured that hegemony which she is still enjoying in a remarkable degree. Besides Surat, Calicut and Maslipatam were also large centres of the export trade.

Early Modern Cotton Trade.

But throughout all these centuries, commencing with the establishment of the first factory in 1612 at Surat, cotton and cotton piece-goods formed the principal and most valuable export trade. The earliest mention of this raw material as an article of trade is to be read in Hakluyt's collection of voyages from a work called "The Process of English Policy," published in 1430. It is stated therein that "Genoa resorts to English ships which bring silk, paper, wool and cotton from India." It is generally presumed that Indian cotton reached the European countries *via* the Levant. The Levant trade was captured by the Dutch, after the Genoese. Beyond the Hakluyt collections, there was another book published in 1621 by one Mr. Munn, and entitled "Treatise on the Trade of India." In this work cotton was mentioned among other articles as imported from the Mediterranean. There is no doubt that England, before the discovery of America, was supplied with Indian cotton by the Levantine traders, the successors of the

Venetians in the trade of India. Mr. William Milburn, in his well-known compendious history of Indian cotton, relates that in 1641 it was stated that "the town of Manchester buys cotton wool in London, that comes first from Cyprus and Smyrna." This would lead us to infer that very little of the fibre at the time was imported from the West Indian Islands. A law was passed in 1660 prohibiting the landing of any cotton which was the growth of Asia, Africa and America except in the English dominions.

The following interesting statistics of cotton imported in Great Britain, on Mr. Milburn's authority, may be given:—

	In million lb.
Imported in 5 years, 1701 to 1705	5·854
,, ,, ,, 1716 to 1720	10·866
,, ,, ,, 1771 to 1775	28·822
,, ,, ,, 1776 to 1780	33·530
,, ,, ,, 1781 to 1785	54·709
,, ,, ,, 1786 to 1790	127·216

But even more interesting is the following table, which informs us of the cotton consumed in manufactures in Great Britain from 1793 to 1799, including the quantity imported from the East Indies:—

	In million lb.		
	East Indies.	Other ports.	Total.
1793 . .	0·760	18·059	18·820
1797 . .	1·353	21·820	23·174
1799 . .	6·934	36·279	43·213

Taking 1799, it may be further instructive to learn which were the countries whence England imported the largest quantities of the raw staple:—

	In million lb.
From Portugal	8·130
,, American States	7·170
,, British West Indies . . .	6·857
,, Asia (India)	6·934

Here are some figures of cotton imported from India by the East India Company in 1805, and by private individuals:—

1805.	In million lb.		£
East India Company .	2·769	valued at	157,000
Individuals	3·665	,,	228,000

The East India Company, from the commencement of the nineteenth century, were exceedingly keen on the improvement of cotton and the extension of its cultivation. The era of the steam engine and of the Arkwright spinning machinery had begun, and Manchester was thus favourably situated to forge ahead and compete with Indian-made cotton piece-goods. An idea of the extent of the exports, both of cotton and piece-goods, from Bombay and Surat in 1805 may be gathered from the following:—

Cotton valued at 85·67 lakh Sicca rupees.
Cotton piece-goods at 53·00 Sicca rupees.

The best cotton of that time was "Surat," a generic name for the varieties of the staple grown in the various districts of Gujerat, of which Surat city was certainly the great *entrepôt* of trade with the West. This appellation continued till "Dhollera" superseded it during the course of the great American Civil War of 1861–65, and thereafter, in its turn, "Broach" was considered as a class by itself of the finest quality, apart from "Fair Dhollera." It remains to be seen when, by the exigencies of trade, "Broach" may share the same fate as the other two, having regard to the notorious fact that the description generally known as "Broach" has also vastly deteriorated in recent years. However, "Surat," at the very beginning of the nineteenth century, held a supreme place among the spinners and weavers of Manchester, and it may, therefore, not be uninteresting to give a few facts as to what it cost, laid down in Liverpool. In 1805 the staple was selling at £22 10*s.* (calculated at 2*s.* 6*d.* exchange) per candy of 784 lb. The charges of conveyance to Bombay, baling and shipping, came to about Rs. 16 per candy, including merchant's commission at 5 per cent. And here two important items of charge, now bulking so abnormally high, namely, exchange and freight, may be considered. The balance of trade was no doubt in favour of India while Council Bills and other latter-day forms of remittance, so familiar to us all, were unknown. The ruling rate of exchange was 2*s.* 6*d.* per rupee against the average 16*d.* rupee of the opening days of the twentieth century. Freight, again, came to £22 per ton! This was payable at ninety days' sight after the arrival of the ship; while the rate of insurance was 7 per cent. on the value of the cargo. These facts as to Indian cotton at the commencement of the nineteenth century are now only of antiquarian interest. Still, they enable the modern trader in this commodity to realise the vast transformation that has taken place during a hundred years. The Surat cotton of old used to arrive in Bombay in native craft from Surat, Bhavnagar, Porebunder, Verawal, and other minor ports. Native craft still continues to ply in spite of railways and steamships. Whether it is a dhow, or a prow or a bugla, there it is, and can be seen any day riding at anchor in Mody Bay in the Bombay harbour. The pier where the cotton was landed was of a primitive character. It was even primitive, or only a little improved, during the stirring days of the American War. Apollo Bunder, as it was

called, was crowded to a distance, from the landing, of a couple of hundred yards with "docras," or unpressed bales. These had to be conveyed to the nearest cotton presses round about the custom-house in the Fort or at Colaba to be pressed and baled. But between the period of arrival and shipment a greater part of the cotton had to be warehoused and piled, also in primitive fashion, by a gang of coolies. The old bullock cart, still an institution in Bombay City, but destined in a few years more to be superseded by the motor lorry, was the only conveyance. It could accommodate only two docras. So an idea may be formed of the exceedingly laborious method of their haulage and final shipment in the old wooden ships. Cotton-ginning and cotton-presses have sprung up all over the country, more or less in the vicinity of towns where the raw staple is brought from the seats of production to be marketed. Their growth is nearly coeval with that of cotton-spinning and weaving factories, of which Bombay City and the city of Ahmedabad are the great strongholds. Hand-ginning of the rudimentary type known from time immemorial was the only method of separating the lint from the seed before the advent of the machine-gins and presses. It is still in vogue in distant villages, where those curious to learn all about the raw staple and its manipulation in this ancient country may see it at work. Indeed, many a process of cotton, from the first to the last, from ginning to spinning and weaving, all by manual labour, can be inspected in some of the villages where the hand-loom industry is still in a fairly flourishing condition.

Raw Cotton.

It is needless to observe that soil and climate have a great influence on the length and strength of the raw material. The Levantine species has little or no colour. The North American variety is white, the South American yellow, the Egyptian brown. In India all varieties may be obtained, according to the soil in which the plant is cultivated. Yellow cotton is held to be superior in point of fineness. Indian conservatism in matters of cultivation generally is well known, and cotton is no exception. The method of growing it is practically that which generations of agriculturists have followed, from father to son, from historic or even prehistoric times. Indeed, experts in Indian agriculture, invited from England and other countries of the West from time to time, have each and all been convinced that the Indian cultivator has very little to learn. No doubt intensive farming in a scientific manner might revolutionise the methods of cultivation in vogue. But that change demands as a precedent condition two important factors. Firstly, the comparative prosperity of the peasant; and, secondly, agricultural education on which the great civilised Governments of the West have spent and are spending enormous sums of money. Impecunious as is the average Indian cultivator of the soil, and plunged as he is in a morass of indebtedness, he cannot afford to apply the costly methods of intensive culture unless the Government comes to his aid in more ways than one. In the first place, agricultural credit and agricultural organisation have to be established. There are a few co-operative credit societies for helping the agriculturist; but at the best these are only a fraction of the immense number which are needed to supply the immediate pecuniary wants of the ryot if he is to raise his crop even in a single year. No doubt the Government has become alive to the necessity of agricultural credit, but only during the last fifteen or twenty years; and some progress may be witnessed later on, especially if the report which the Cotton Committee, who have now gone round the country, may make in reference to extended cotton cultivation and cotton improvement is accepted by the Government, and the recommendations they may make are practically attended to in a reasonable time. Secondly, the economic condition of the ryot, depressing as it is and far from prosperous, demands amelioration to a considerable extent. Until the ryot is lightened of his burden of annual assessments, which in the ryotwari tracts, especially the Presidencies of Bombay and Madras, are liable to revision every thirty years, it is hopeless to expect any amelioration in the pecuniary condition of the ryot.

Opinions differ on this vexed subject, as to whether the land revenue assessments in all parts of the country are or are not heavy enough, and whether the State does not absorb too large a measure of the product of the toiling peasant. There has been wrangling over this problem for the last fifty years at the least, without any definite conclusion. In this matter much might be learnt from the able minute of the late Sir Louis Mallet, written as far back as 1876, when he was Under-Secretary of State for India. One pertinent extract from the minute may be

quoted: "On the one hand, we see a system which sweeps into the coffers of the State 50 per cent. or more of the net produce of the soil, thus diverting a fund which, in countries where private property is absolute, would, to a great extent, find its way back again into channels of agricultural improvement. But the amount of produce thus diverted is not only large, it is also uncertain. The percentage itself is uncertain, varying with the views of successive Governments; and the amount actually assessed, even within the prescribed limits, is uncertain, varying with the accidents of seasons, with the character of the cultivators, and with the judgment and knowledge of the settlement service. . . . There is a marked absence of any adequate accumulation of capital upon the soil, and, as a consequence, of any sufficient appropriation of such capital to purposes of agricultural improvement, deficiency of stocks, of manure, of roads, of tanks, often of seeds, of implements."

Sufficiently serious attempts have not yet been made to diminish the burden of the ryot's heavy indebtedness, which hangs as a millstone round his neck. Agricultural relief legislation in the past, in some provinces, has been proved to be a comparative failure after many years' operation. The institution of agricultural banks with ample capital in each province can only relieve that indebtedness in thirty or forty years. But it is a matter of profound regret that the State has not as yet taken effective action with the object of diminishing this load of debt, which has been variously estimated at from 250 to 350 million pounds sterling.

So far, then, as to the ills from which the Indian peasantry has been suffering these many years past for want of a more active policy. Then there is the entity of the sowcar or money-lender. In reality, he is the saviour of the peasantry rather than the bloodsucker as he is generally represented to be, seeing that in the agricultural economy of the country he discharges a most useful function, in spite of his usury. One has only to imagine the sorry, nay, most pitiable plight in which the Indian peasantry might have been for years past but for the intervention of this most useful factor in Indian agricultural economy. Where would have been those larger exports of staple commodities but for the initial monetary assistance which the money-lender renders to the ryot; and where would have been the "growing" land revenue which is deemed the "backbone of Indian finance"? The fundamental relief lies in the direction of lightening the ryot's burden of revenue assessments, which are periodically enhanced for one reason or another, and the correctness of which unofficial experts, fully conversant with the condition of the peasantry, have repeatedly challenged. A prolonged and bitter controversy on the subject of taxing the improvements made by a ryot at his own cost raged in the Bombay Presidency some years ago.

Secondly, the institution of land banks, which could cautiously advance all the money needed for carrying on ordinary seasonal cultivation. With two such aids the ryot could diminish his cost of production and the interest charge on his debt, thus considerably improving his present most miserable economic condition.

And, thirdly, elementary education, especially in practical agriculture, which may prove highly useful to the rising generation of agricultural youths—an education which would enable them to realise how efforts by economy and labour-saving appliances could be made to grow two blades of corn or cotton where one is grown now. The moral duty of the State to give elementary agricultural education has been woefully neglected till lately; though it is some comfort to notice here the attempts which the Government of India has been making these few years past in reference to this subject. In short, the State in India has to take a leaf out of the book of the practical agriculturists of the United States and its Government in order to achieve the great object of extended and improved cultivation, not only in cotton, but in the many staple commodities which are so peculiar to India.

Cotton Cultivation.

It is not yet possible to state with certainty the actual area under cotton cultivation in India, though in recent times, thanks to the energy, industry and intelligence of the experts who have from time to time presided over the Statistical Department, there has been noticed a vast improvement in obtaining as accurate information as possible; and Mr. Findlay Shirras, the present Director of Statistics, has spared no pains to make his annual cotton forecasts reliable. It may, however, be said that, during the last twenty years, there has been a marked increase in the area of cultivation. Before the latest statistics for the current year are exhibited, a brief survey may be taken of the condition

as it was just a year or two before the American Civil War, which, it is superfluous to say, gave the first great impetus to cotton cultivation. In 1859 the exports amounted to 642,000 bales of 400 lb. each. Taking the yield, at the time, at 60 lb. per acre, the area then under cotton might be fairly computed at 4,280,000 acres. But this excludes the area then cultivated for home consumption. It is impossible to estimate the acreage, but it must be many lakhs. In 1864–65, the most critical year for the Lancashire cotton industry, the exports of Indian cotton had reached on an average 973,000 bales. This, at the rate of 70 lb. per acre, would give an area of 5,760,000 acres, an increase of 34 per cent. over 1859. Coming nearer to our own times, a fair idea of the area under cultivation may be gathered from a comparison of two periods, say, 1874–75, when cotton factories began to spring up in Bombay in larger numbers than at any time during the previous twenty years — the first factory was established in 1853 by an enterprising Parsi merchant, the late Mr. Cowasji Nanabhoy Davur—and 1888–89, when the acme was almost reached, after the continuous and steady growth of spinning and weaving mills in Bombay and Ahmedabad.

Area under Cotton Cultivation.

	In lakhs of acres. 1874–75.	1888–89.
Bombay and Sind	42·26	52·68
Berar	19·56	19·94
Central Provinces	8·05	5·96
United Provinces	10·87	13·05
Oudh	00·39	00·59
Punjab	7·10	7·56
Madras	15·77	14·65
Total	104·01	114·43

The increase amounted to over one million acres. This was exclusive of the acreage under Native States, for which reliable statistics are still wanting. The cotton crop estimates for 1917–18 may now be given, as the latest available. These are taken from the *Indian Trade Journal*, of which Mr. Findlay Shirras is the editor:—

Area under Cultivation and Yield per Acre.

	Acre in lakhs.	Yield per acre in lb.
Bombay, including Native States	66·70	74
Central Provinces and Berar	45·64	52
Madras, including Native States	25·24	79
Punjab do. do.	17·40	65
United Provinces do.	13·16	60
Sind do.	2·20	142
Burma	2·36	59
Behar and Orissa	0·67	95
Bengal, including Native States	0·71	113
Frontier Province	0·38	105
Assam	0·32	150
Ajmere-Merwara	0·47	111
Hyderabad	34·45	52
Central India	13·94	50
Baroda	8·27	105
Rajputana	4·27	80
Mysore	9·50	48
Total	237·68	Average 66

It will be seen that the average yield is 66; but the yield varies, going as high as 142 in Sind, 150 in Assam, and 113 in Bengal, and as low as 52 in Hyderabad and 60 in the United Provinces. It must be reserved to the Cotton Committee to fully explain the cause or causes of such variations, showing a maximum difference of 51 lb. The fact, however, shows that in certain provinces there is room yet for great improvement, albeit the average yield now obtained in India is low compared with that obtained in Egypt and the United States. Once the causes contributing to the comparatively poor yield are definitely investigated and ascertained, and remedies suggested whereby both the quantity and the quality may be improved, the cultivation of Indian cotton will leave little to be desired, though the problem of the extended cultivation of the long-stapled varieties will still remain to be solved.

Trade Descriptions.

Indian cotton, as far as exports are concerned, is sold according to the descriptions generally standardised by the chief cotton traders. These are "Oomras," "Dholleras," "Bengal," "Broach," "Westerns," "Coconadas," "Tinnevelly," and "Compta Dharwar." The Oomra descriptions have the largest acreage of all, and, therefore, the largest production of bales of 400 lb. each. The raw staple coming from Berar, Barsi and Nagar, from Khandesh, from Central India and from the Central Provinces—all these are included in "Oomras." Berar and Barsi yield the largest production; the number of bales for the former for 1917–18 are given at 4,28,000, and for the latter at 4,41,000. The Dhollera varieties are estimated at 5,98,000; the Bengals, including those from Sind-Punjab, at 7,05,000 bales, and Broach at 3,20,000 lakh bales. The total is estimated at about 40 lakh against 44 lakh in 1916–17.

Exports.

The bulk of the Indian cotton is exported to Japan. The share of Japan during the five years ending 1913–14 averaged 42 per cent. of the total exports. Germany's share came to 14·5, and Belgium's to 11·5 per cent. The United Kingdom only imported 5 per cent. In 1917–18, Japan's share came to as much as 68 per cent. while Italy's was 11·4, and the United Kingdom's 9·4 per cent. Prices have undoubtedly mounted higher and higher while the quantity of exports has somewhat decreased, say to 425,000 tons against the average of 430,000 tons ending with the quinquennial period from 1909–10 to 1913–14. The values as recorded are for an average of five years ending:—

		Millions £.
1913–14 =	33·27 crore rupees =	22·18
1915–16 =	24·92 ,, ,, =	16·61
1916–17 =	34·18 ,, ,, =	22·72

Cotton Factories.

Calcutta claims the honour of having established the first cotton-mill in India. The Goosery mill was erected in 1838, but for many years nothing was heard about its working. For all practical purposes, it may be fairly said that the first foundation of the producing of yarn and cloth by steam-power was laid by Mr. Cowasji Nanabhoy Davar, to whom I have already referred. He was also the pioneer of what may now be called *swadeshi* ! (indigenous) banks in India, and he built the first ice factory in Bombay. His bank, which was called the "Central Bank of Western India," took its birth in those stirring days of the American Civil War when, flushed with the large profits in cotton, a variety of banks and financial institutions sprung up in Bombay only to come to grief soon after the close of that war in 1865. Mr. Cowasji started his cotton-mill with only 5,000 throstle spindles. As a youth the writer saw it in 1856, when it was in full working order and yielding a handsome profit to the owner. The mill is still standing, albeit greatly enlarged. About the same time an Englishman, Mr. Landen, is said to have started a small factory in Broach, but nothing much was heard of it for some years, when it developed into a fairly large mill. Mr. Cowasji may therefore be rightly considered the founder of the cotton industry in India, and his name deserves to be perpetuated for the great impetus his enterprising talents, his patience and perseverance gave to it. Between 1853 and 1874 the number of mills rose to nineteen in the Island of Bombay; but till that period it is not known that a single cotton factory had been established elsewhere, save one or two in the city of Ahmedabad. The earliest of the Bombay mills were the Oriental, the Manekji Petit, the Alliance, the Great Eastern, the Coorla, and the Morarji. Excepting the Alliance, all were spinning and weaving mills. Their founders, shrewd men of business as they all were, and more or less importers of Lancashire piece-goods, from the very first had clearly realised the importance of manufacturing cloth suited to Indian consumers. The great rise in the price of the raw material, which had reached the phenomenal figure of Rs. 600 per candy, had the blighting effect for the time of suspending work, it being impossible to manufacture cloth of the coarser descriptions only at the enhanced price of cotton. In fact, the early mills had to shut down till some time after the restoration of peace in the United States, when, of course, the price declined to normality. The revival of trade and credit in Bombay, which had been at its lowest for the first five years after the collapse of the share speculation, somewhat akin to that of the South Sea Bubble mania, soon led to the capitalists embarking on the cotton industry, which they quickly realised was most profitable and suited to the conditions of the rising city. It was also seen that there was a considerable field for their enterprise in areas bordering on the cotton-producing districts. Mr. J. N. Tata was the very first to seize the opportunity of establishing a factory at Nagpur, and he was closely followed by Mr. Morarji Goculdas at Sholapur. The Empress Mill, Mr. Tata's concern at Nagpur, started working on January 1st, 1877, and the name had its origin in the proclamation on that day of Queen Victoria as Empress of India. The opening of this and the establishment of the Sholapur Mills were events of no little importance in the industrial annals of the country, as they were really the pioneers of cotton-mills outside Bombay. They paved the way for the establishment of many mills, first in the Presidency of Bombay, notably Ahmedabad, and later in other parts of India, chiefly in the cotton-growing districts. But this rise of mills in the seventies seems to have alarmed Lancashire. Locally-made yarns, chiefly of 20' counts and those below it, had been considerably displacing Lancashire, so also some of the coarser descriptions of grey goods such as T. cloths and Domestics. Hence Manchester succeeded, in

1877–78, in getting the House of Commons to pass a resolution to the effect that "in the opinion of this House, the duties now levied upon cotton manufactures imported into India being protective in their nature, are contrary to sound commercial policy and ought to be repealed without delay as soon as the financial condition of India will permit." Famine conditions of a severe character then generally prevailing in the country prevented the Government of India and the Secretary of State from carrying out the resolution. But on March 13th, 1879, the first step in the ultimate repeal of the import duty on cotton goods from Lancashire was taken. The repeal, it may be stated. was first mooted in 1875 during the Viceroyalty of the late Lord Northbrook, who, however, refused to adopt the policy suggested by Lord Salisbury, the then Secretary of State. Even in 1879, the financial condition was far from prosperous. The country, in the first place. had not yet emerged from the effects of the famine conditions which had prevailed during the preceding two years, and, in the second place, the Second Afghan War had considerably embarrassed the Indian treasury, and a huge deficit was afterwards discovered. The repeal in 1879 was confined to the coarsest class of Lancashire grey goods, the amount which the Indian revenues had to sacrifice being £25,600. This repeal did not satisfy Manchester. The resolution passed on March 13th, 1879, was to the effect "that the Indian import duty on cotton goods being unjust alike to the Indian consumer and the English producer, ought to be abolished, and the House accepts the recent reduction in those duties as a step towards that total abolition to which Her Majesty's Government are pledged." The finances of the country were so greatly disturbed by the Afghan War that nothing could be done till 1882–83. Lord Ripon, a staunch Free Trader, was the Viceroy, and Sir Evelyn Baring (the late Lord Cromer), also a robust Free Trader, was the Financial Member. They both made India a free trading country, having abolished all import duties, including those on piece-goods.

At the date of the repeal of the duty on the coarser kinds of Lancashire piece-goods the number of Indian cotton-mills had risen to 58, and there is no doubt that the abolition of all duties, in 1882–83, gave a great stimulus to the multiplication of cotton factories in the country. Practically the eighties of the nineteenth century witnessed the largest number of new mills, not only in Bombay but elsewhere. The number, which was only 58 in 1878–79, rose in 1888–89 to 114, say an increase of 64 mills, of which no less than 29 were established in the city of Bombay alone. The spindle strength increased by 1,200,000 and looms by 10,385 :—

	No. of Mills.	Spindles.	Looms.
1888 . .	114	24,88,851	19,496
1878 . .	58	12,89,706	9,111

The momentum which the industry acquired in that epoch-making decade continued, with more or less force, till the outbreak of the present war. The progress from 1889 to 1914 will be seen from the following :—

	Spindles.	Looms.
1914	67,78,895	1,04,170
1888	24,88,851	19,496
Increase .	42,90,044	84,674

Within a quarter of a century India's spindle power has increased 172 per cent., and loom 434 per cent. In 1916, the spindles had increased in number over those of 1914 by 60,892, and the looms by 6.089.

Thus during the last forty years and more India has undoubtedly forged ahead in placing the industry on a sound and prosperous footing. But great as this accession to her spindle and loom strength is, it is needless to state that it is far below that of the United Kingdom. The following figures show how, in the competitive race of the cotton industry, the United Kingdom is immeasurably far in advance of India.

1916.	Spindles.	Looms.
United Kingdom .	5,98,11,222	8,08,796
India	68,39,877	1,10,268

How do Great Britain and India stand in this respect in comparison to their respective populations?

	Spindles. Per 1,000.	Looms. Per 1,000.
United Kingdom . .	318·2	17·8
India	21·7	0·35

These figures plainly show that it will be a long long while before India can hope to boast of the strength which Great Britain now enjoys in the cotton industry. And while that is the case, and while the long-stapled variety of cotton is yet as far distant from realisation as it was fifty years ago, it may be reasonably inquired whether India can displace the enormous import of piece-goods, which at the end of 1914–15 amounted to 2,420 million yards, valued at £28·4 million.

But at this stage it is essential for the purpose of a clear comprehension to exhibit the figures of the production of yarn and cloth, say, for

the quinquennial period which ended March 31st, 1914, and for the triennial period which ended March 31st, 1917.

	Yarn in core lb.
1912–13	68·84
1916–17	68·05

There is a diminution of 79 lakh lb., which may be deemed almost negligible. The production has fluctuated, but has not again reached or surpassed the figures of 1912–13. At the same time, part of the diminution is owing to the spinning of higher counts. There has been an increase in the production of higher counts to the extent of 2·29 crore lb. between 1914–15 and 1916–17, whereas in the lower counts, say, from 1 to 20, there has been no increase to speak of. This will be clearly perceived from the following comparative table:—

	In crore lbs.		
Low counts.	1914-15.	1915-16.	1916-17.
1 to 10	13·10	14·53	11·06
11 to 20	34·33	38·62	36·95
	47·43	53·15	48·01
Higher counts.			
21 to 30	15·62	16·97	17·14
31 to 40	1·87	1·86	2·40
Above 40	0·22	0·19	0·46
	17·71	19·02	20·00

It should be noted that it is more or less due to the larger demand of 30's, the imports of which have considerably dwindled, with higher prices, that Indian mills increased their output, and not for purposes of weaving, which is still next to nothing. This will be seen from the following figures:—

	In crore lbs.		
	1914-15.	1915-16.	1916-17.
English (mule and water), 26 to 30	0·47	0·32	0·09
Indian, 30	1·96	2·04	2·32
English, 41 to 50	0·29	0·27	0·13
,, 50 and above	0·28	0·30	0·19
Indian, 40 and above	0·22	0·19	0·46

When the Lancashire mills are again in full swing after the war, it may be taken for granted that Lancashire yarns from 30's and upwards will largely overtake the Indian production. It is well known that hand-loom weavers, who are the largest consumers of English 30's, prefer the English to the Indian on account of its great superiority. It should also be remembered that the exports of Indian yarn have been declining since 1913–14. The reduction is as follows:—

	In crore lb
1912–13	20·39
1913–14	19·80
1914–15	13·36
1915–16	16·02
1916–17	16·04

What the Indian mills have lost in the exports of yarn has been made up in the exports of cloth. In other words, more yarn has been woven into cloth for home consumption and foreign demand. There is nothing very extraordinary in this condition of the Indian industry. Apart from China, the largest importer of Indian yarn is Persia, where the quantity imported from India during 1916–17 was 51·08 lakh lb., against only 17·67 lakh lb. two years ago. Minor countries have also been large absorbents. Their imports during 1916–17 came to 65·64 lakh lb., against 26·28 in 1914–15. Japanese yarn is undoubtedly fast replacing Indian in China, and it is quite possible that within the next few years Indian exports to that country will be more or less negligible. It is to be presumed that India will have a larger market after the war in Asiatic Turkey, and new markets in East and West Africa. But the larger the quantity of indigenous yarn that is consumed in the manufacture of cloth, the less will be the exports to the new markets unless the production is greatly stimulated. That will largely depend on the extent to which India increases her spindle strength after the war. Indian mills, which are now reaping a rich harvest of profits, are wide awake, and the more sagacious and well-financed are carrying large reserves to depreciation and renewals of machinery to meet future requirements.

Coming to the production of piece-goods, mostly grey and dyed, it may be observed that till 1907 the number of power-looms in all India was only 58,436. But there was a considerable spring forward in 1908, as many as 9,484 looms being added. This brought the total to 67,920, till in 1910 it reached 82,725. In 1912 it was 88,951, and in 1916, as already pointed out, it was 1,10,268. Thus in nine years the loom power has increased nearly 90 per cent., while there is little doubt that the post-war period will witness a considerable accretion. Of the increase of 51,832 looms in all India, the share of mills in Bombay City alone come to 21,223, that is to say, against 31,982 in 1907, there were 53,205 in 1916, the balance of 30,609 being distributed over all the other parts of India.

The annual average of cloth production in the Indian mills during the decennium ending 1910–11 was 16·45 crore lb., but in the last year the figures recorded were 23·09 crore lb. In 1911–12 the output rose to 25·21 crore lb., while the production since was as below:—

	In crore lb.
1913–14	27·44
1914–15	27·70
1915–16	35·22
1916–17	37·73

The production during the last three years has mounted up to 37·73, say an increase of 10·03 crore lb.

It is, however, necessary at this stage to analyse the output in its two-fold aspects. Indian cloth may be divided into two broad divisions, namely, grey and coloured piece-goods. Bleached goods are yet in their infancy, but there is a great potentiality in these, as the more important factories have bleaching plants on a scale which will commercially pay. There is only one such fully equipped in Bombay City. A few others have bleaching plants, but for all practical purposes they are negligible at present. The output of the two groups may be exhibited for the latest triennial period, ending March 31st, 1917, as under:—

	In crore lbs. Grey.	Dyed.
1914–15	21·36	6·10
1915–16	26·72	8·16
1916–17	27·46	9·82

The increase in the output of grey goods was 6·10 crores, equivalent to 28·5 per cent.; while that in dyed goods was 3·72, equivalent to 61 per cent. This plainly indicates that the coloured stuffs have made in the triennium highly gratifying advance. The rate of the progress was double and a little more over that of grey. The reason is not far to seek. Owing to the diminishing imports of dyes from Germany, the market for anilines and alizarine colours began slowly to rise till at last fabulous prices were demanded by the handful of traders in dyes. This led to a keen scramble to buy, and speculators forced prices up. Indeed, the dye trade in Bombay City was for a time a pure gamble, and the man in the street who sometimes tried his luck with a few rupees in his pocket would often end the day with a heavily-laden silver pocket. Public opinion, however, denounced this speculation and it died away. The mills bought all that could be had, while the profiteering traders managed to conceal their stocks, thus creating an artificial scarcity in order to further inflate the prices. But in spite of the enormous prices per pound at which mills acquired the principal colours, there was such a keen demand for coloured goods, by reason of the material decline of imports from Lancashire, that the output of dyed goods in Indian mills rose to phenomenal figures, while the profits earned were equally phenomenal. In this respect the following table is most interesting. During the last year of the pre-war period the imports of English dyed goods was 68·22 crore yards and the output of Indian mills 30·62:—

	In crore yards. 1912-13.	1914-15.	1915-16.	1916-17.
English Grey Goods . .	153·61	129·46	109·90	76·20
Indian Grey Goods . .	91·41	88·05	109·48	113·48
English Coloured Goods . .	68·22	46·36	32·25	40·37
Indian Coloured Goods . .	30·62	25·52	34·66	44·16

This table tells most eloquently the effect of the decline of the imports of Lancashire grey and coloured goods in India and the increased production of the grey and coloured goods in Indian mills.

	Per cent
(1) English grey goods imports declined	50·3
(2) English coloured imports declined .	41·0
(3) Indian grey goods output increased .	24·1
(4) Indian coloured output increased .	44·2

I now turn to the second aspect of the comparative analysis, namely, descriptions of grey goods. Here it should be explained that Indian mills produce some varieties, such as grey "chadars," which are not imported into India. Again jacconets and mulls imported from Lancashire are hardly produced in any quantity at all. And as to coloured goods, Lancashire exports a variety such as cambrics, madapollams, muslins, mulls, jacconets, dhutis, drills and jeans, saris, shirtings, twills, printers, etc., of which Indian mills only produce checks and perhaps a few negligible varieties. So there can be no manner of comparison between the coloured goods imported and those manufactured in the country.

The class of goods in which there is a marked increase of yardage is longcloths and shirtings. English imports before the outbreak of the war totalled 539 million yards, and by 1916–17 these had declined to 155 million yards. Meanwhile Indian-made longcloths and shirtings,

which were 292 million yards in 1913-14, had risen to 426 million yards. It must be remembered, however, that quality for quality Indian longcloth is not identical with the English. It is well known that the former is made from 24's weft and 22's warp. The English is of higher counts than these. It may be that here and there some mills are turning out the same quality as the English, but it will be found on accurate investigation that the quantity produced is perfectly negligible.

It is not the object of this paper to enter into the vexed controversy of protection and substitution in connection with the import duties. That controversy must be decided on its own merits and on the basis of ascertained facts. But this much may be stated here that Lancashire's apprehension about the competition of Indian mills in the description of the greater bulk of grey, white and coloured goods is unfounded, for the simple reason that India has not yet been able to provide herself sufficiently with long-stapled cotton from which the goods could be manufactured. Rather Lancashire should be apprehensive of the strides Japanese goods are making in the common market of India where Lancashire exports her goods. Japan has the great advantage of using American cotton for her cloths, and her mills have for some time past been steadily pursuing a policy of turning out goods of Lancashire descriptions to sell side by side in the Indian markets. Here are some figures:—

In 1912-13 the total imports of piece-goods from the United Kingdom and foreign countries were 298 crore yards, while that produced by the Indian mills came to 122 crores—in all, 420 crore yards. In 1917, owing to the sharp decline of Lancashire imports, the total came to only 189 crore yards. But the Indian mills produced 158 crore yards, so that the total reached 347 crore yards. This was 73 crore yards less, while the population meanwhile has been greatly on the increase. Practically, taking the census population at 31 crores, there were 13·55 yards per head, against 11·20 in 1916-17. Of course, the production of handlooms, an unknown quantity, should be added to these quotients.

CONCLUSION.

At the end of March, 1917, there were in India, including Native States, 266 cotton-mills, of which 85 were situated in the city of Bombay, 94 in the Bombay Presidency, 18 in the United Provinces, 14 in the Madras and 14 in the Bengal Presidencies, 7 in the Central Provinces, 7 in the Punjab, and the rest scattered in the other provinces. Their combined capital aggregated 19·63 crore rupees, say, 13·08 million sterling. Of this 7·95 crore rupees belonged to Bombay City, and 4·68 crores to the various towns in the Western Presidency. Beyond this share capital, it may be assumed, at a conservative estimate, that 10 crores more were invested as loanable capital for working purposes, so that the combined capital might be taken at 31 crores, or £20 million. The total number of spindles was 68·40 lakh, and that of looms 1·10 lakh. The number of workpeople employed was recorded at 2·74 lakh, which signified that 8·22 lakh persons lived or depended on the wages earned by the operatives. Their wages, on an average, would come to about £3·2 million per annum. The total number of cotton bales, of 392 lb. each, consumed by the mills was 21·97 lakh.

Judged by the broad statistics indicated above, it will be admitted that the Indian cotton industry has made, during the course of the last fifty years, steady and substantial progress, which is as creditable to the enterprise, energy, and mercantile acumen of those engaged in the industry, as it is gratifying to the population at large, who are keenly interested in the greater development of all kinds of industries in the country on sound and prosperous lines. The progress made in the cotton industry is an earnest of the strides it may take in the future, perhaps, at a quicker pace than has been the case hitherto. As in other economic matters, so in this, the war has made us unlearn many things and learn many more, and it is quite possible that in some respects the Indian millowners will take a new departure after the lessons the war has taught.

Here it is needful to take into consideration two external factors of a potential character,

which have partially obstructed the larger progress which might have been fairly expected. These are, firstly, the Japanese competition, and, secondly, the political influence of Lancashire. Apart from pushing a variety of her products and manufactures, Japan has taken a bold step forward in placing on the Indian market her cotton fabrics, especially those made from Indian cotton purchased in India. There has been a very large import of unbleached calico, as a beginning only, since 1912–13, as will be evident from the comparative table below:—

	1912-13. £	1916-17. £
Cotton Hosiery . .	415,000	850,000
„ Piece-goods .	73,000	1,621,000
„ Yarn . . .	35,000	354,000
„ Sundries . .	16,000	217,000
	539,000	3,042,000

An increase of from half a million to three million sterling in the short space of four years tells its own tale of the strides the Japanese industrial giant has made. Of course, the leaders of the Indian cotton industry say that so long as the British Government refrains from placing an export duty on the raw cotton which Japan buys from India, averaging in value about £12 million, the Indian cotton industry is placed at a great disadvantage. It might have been a different story had Japan grown her own cotton from which to manufacture her fabrics and export them to India for competition with Indian cotton products. But such is not the case. The bulk of her yarn and piece-goods is manufactured from cotton bought in India. She has already replaced in the Chinese market more than half the quantity of yarn which India used to export ten years ago. And she is strenuously endeavouring at the present time to push her cloths. That is the prime factor involved in the unequal competition. Next is the question of freight. The freight is of a two-fold character—freight for the conveyance of the raw material to its destination, and freight for the transport to India of the manufactured cotton goods. The cost of such double freight would ordinarily prevent any manufacturer from competing with Indian cotton goods. But in the case of Japan, the freight to and fro is believed to be subsidised. Thus the cost of production stands on a par. Of course, the Japanese have some local advantages, one being cheaper labour, though even in Japan labour is becoming more expensive. The difference is not in the wages of the operatives. These are almost equal. The average wage earned by a Japanese male operative is 12½ annas, by a female 8¼ annas, per day. But the proportion of male to female workers is just the opposite of what is generally the case in India. In Japan, the percentage of female operatives to males is as ¾ to ¼. Necessarily the cost of wages is advantageous to the Japanese spinner compared to the Indian. There are other minor advantages, for example, the daily average working hours come to 22·16, while the monthly average working days are 27·25. Necessarily the daily spindle production is greater. But all the local advantages do not and cannot outweigh the immense saving in freight. Practically, cotton is moved free to Japan, and cotton goods are transported back to India free, or almost free. There are those who, carefully watching the present triangular character of the competition prevailing in India, do not hesitate to forecast the probability of Lancashire goods having to bear the stiff competition of Japan in the Indian markets. For, since the war began, there is to be noticed the unusual phenomenon of Indian, Japanese and Lancashire piece-goods struggling to make a headway. The struggle is yet at its beginning. But Japan has only by a variety of methods to push these goods, even at a loss for a time, till she has obtained a strong foothold in the country. That there is every reason to believe that she will gain such a foothold goes without saying. Under the circumstances, it may be asked whether it is not Lancashire's interest to see that it is not slowly driven away from some of its best markets in India. Some Indian politicians have more than once suggested an export duty on cotton, but thinkers of the opposite school assert that such a duty would greatly disadvantage the Indian ryot. An export duty on cotton by cheapening the raw material might discourage the Indian cultivator, and induce him to substitute other crops, thus reducing the total available supply of cotton. If, however, there were to be a growing demand from Great Britain for it there could be nothing to prevent India extending her area for this material, seeing she must be taken now as an integral part of the British Empire. The whole problem of an export duty no doubt bristles with difficulties which, it is to be hoped, fair-minded British statesmen who mean well to India, and who are sincerely desirous of advancing her commercial and Indian interests, will attempt to solve to the satisfaction of the Indian people. Otherwise foreign industrial

penetration now springing up might grow to gigantic proportions in the future, prove vastly detrimental alike to Indian and Lancashire interests, and be most difficult to overcome later.

The second external factor which has somewhat hampered the progress of the Indian cotton industry is the action Lancashire has from time to time taken in reference to import duties, excise and the introduction of factory legislation. Attached to no party and interested only in the greater welfare of Indian cotton industry, the present writer ventures to make the following observations in a spirit of the utmost fairness and candour. He is himself a convinced Free Trader, and on many points is generally in agreement with the views of Manchester. The men of Lancashire are perfectly aware of the opinion entertained, not only by Indian millowners, but by the enlightened section of the entire Indian community, that whenever occasion demands they are not backward, by reason of the great political influence they command in the House of Commons, to press their own wishes on the Government at home in matters where they apprehend their special interests are at stake. This kind of pressure, it is urged, has been more than once exerted during the last forty years; which, in the opinion of the Indian millowners, has been most prejudicial to the interest of the great industry in which they are engaged. The steady and substantial progress which the Indian cotton industry has continued to make since 1880 might have been greater but for this pressure. Indian millowners are convinced that the pressure is exercised because of the apprehension, if not the alarm, felt by Lancashire about the material curtailment of its piece-goods trade in the Indian market as cotton-mills grow in number and in the strength of the spindles and looms. The apprehension, say the Indian millowners, is natural, but they seriously doubt whether the method and manner adopted by Lancashire are justifiable, namely, using their great political influence in and out of the House of Commons to urge Ministers, be they Liberal or Conservative, to ask the Indian Government to enact legislation or issue executive orders under the pretext of maintaining the Free Trade policy of the Government at the seat of the central authority or of sanitary benefits for the Indian operative. They question the sincerity of the interest evinced in Lancashire in the welfare of Indian factory operatives, and are disposed to attribute it to a desire to restrict Indian competition. They give instances. The first of such agitation was started in 1875 to abolish the 7½ per cent. import duty on all cotton goods. It was negatived by Lord Northbrook, who declared that the duty was levied for revenue purposes only and the protection theory did not exist. In those days, it is very well known, Indian finances were extremely poor and the sources of revenue exceedingly inelastic. The 7½ per cent. duty was imposed on almost all classes of commodities, including piece-goods. But Lancashire continued the agitation and was able to have the duty removed from the coarser classes of goods in 1878-79. Lord Ripon and Sir Evelyn Baring abolished all import duties except on liquor and arms, in 1882-83. So the agitation against protection died out for a time. But the eighties of the nineteenth century were a memorable period in mill construction. Lancashire was alarmed, so another cry was taken up, namely, the necessity of a Factory Act. It is superfluous to go into the history of that agitation. Suffice to say the enormities alleged against the inhumanity of Indian millowners were carefully investigated by an impartial commission, who proved that most of the so-called facts of the agitators were baseless. All the same, a Factory Act was passed in 1890, regulating the hours of labour and the employment of young persons and women. The Indian millowners have not forgotten that Lancashire agitated for shorter hours in Indian mills. They think the motive was less philanthropy than the curtailment of production. Their impression may be wrong. But there it is.

Subsequently, the closure of the mints and the low exchange, creating a deficit in the revenue, necessitated the reimposition of the import duties. Still later on, the duty on piece-goods was differentially treated, and it was fixed at 3½ per cent. only, while other commodities were dutiable at the rate of 5 per cent. This differential treatment was universally condemned by Indians. Moreover, the plea of protection was again vigorously raised, and under the pressure of Lancashire there came the mandate from the Home Government to impose a countervailing excise duty on Indian-made cloths to appease the Palatine County. The millowners of Bombay strongly protested against the injustice of this imposition by cogent arguments, which have lost none of their force even to-day. The Government acted wisely in levying the new import duty of 7½ per cent. on Lancashire

piece-goods last year, and by doing so have frankly admitted that the former duty was unjust to India. But the Indian millowners still consider that the excise duty of 3½ per cent. ought to go, seeing that it in no way serves as a protection to them against Lancashire goods. The last conviction, which also has a firm hold on the minds of those engaged in the cotton industry, is that the revised Factory Act passed a few short years ago was the result of the self-same pressure which has distinguished Lancashire so far as her trade in piece-goods with India is concerned. It is for Lancashire to remove, if it can, these deep-rooted convictions. But, meanwhile, the opinion is general and strong that all the four episodes above referred to in the cotton industry have to a certain extent hampered the steady progress it has been making since 1880. Thus Japan and Lancashire are considered the two external factors of a most potent character against the further natural development of the Indian cotton industry.

On the other hand, it may not be unuseful to refer to some internal factors also which, in the opinion of the present writer, impede the smooth progress of the industry. These factors are of a twofold character. Firstly, the action of the Indian State in relation to commerce and industry by means of legislation and the pressure which the State brings to bear on owners of cotton factories to undertake primary education for the young operatives and to provide sanitary dwelling-houses for the workers in general. As an instance of the first class of internal factors may be cited the Indian Railways Act of 1890. This enactment has long been the subject of agitation, on the ground that it is one-sided and arbitrary in respect of transport of foreign goods inland. and also in respect of long and short distance freights, which are generally complained of as hampering the free working of large trades and industries. Dissatisfaction in this respect has led to a strong agitation for the complete management of all State-owned railways by the State. The Government has recently invited all important commercial and other public bodies to send in their suggestions as to how far and in what directions the Railway Act can be amended. The other interference of Government has for its object humanity. It is to provide sanitary dwelling-houses for the working-classes. Mill-owners hold that this is a duty of the State, and not of the employers. But the Indian Government has for some time past been mildly coercing employers in the cotton industry *in the city of Bombay only* to provide that accommodation, at the same time expressing its readiness to co-operate with them. But when it comes to the specific nature of the co-operation, it is nothing but a temporary financial arrangement to enable millowners to acquire the needed land, the cost of which has to be repaid by them by instalments, with interest on the sums advanced. In this way the State tries to impose its authority on the millowners and partially hampers their proper working. Of course, it goes without saying that millowners in their own better interests may provide sanitary dwelling-places for their operatives. But it is one thing to do such a work voluntarily and another thing to be compelled to under State coercion. It is this kind of interference to which Bombay millowners object. They ask whether Lancashire millowners are coerced in this fashion by the British Government. There is, again, the education of operatives. The Bombay Government has been off and on urging on the millowners to discharge a duty which throughout the civilised world is undertaken by the State. It is not the legitimate business of millowners. Here, too, there is an interference which is disliked, though, of course, it is no hindrance to the working of mills. The millowners in both cases do not deny their moral obligation. They are ready and willing to co-operate with the Government, and even to contribute their quota, but it is unheard of that such duties in any way belong to those engaged in the cotton industry. Moreover, it is a matter of astonishment that Bombay millowners alone should be thus pressed, seeing that there are only eighty-five mills in the city, or only one-third of the number in all India.

It remains to be seen how, at the close of the war, Indian industries of a variety of character take a new departure. The economic lessons which the war may teach will be of the highest import for the future progress and prosperity of the cotton-mills, as well as for their operatives, who are now beginning to understand their rights and responsibilities, and all about the advantages of higher wages accompanied by shorter hours. They are also growing self-assertive, while their leading men are not slow to acquaint them with the future relations of Capital and Labour. But whatever may be the new departure, it may be taken for granted that the Indian cotton industry has a great future before it, and given the necessary im-

provements still lacking in the internal management, and a better insight into the general industrial problem of the world, a broader view of international trade and of new markets to be tapped, there is not the least doubt that Indian mills will take larger and more satisfactory strides in the future. Millowners will be wise, therefore, in their own interests, to put their house in order from now, so as to be prepared at the proper hour to make a cautious but bold spring forward. It is a settled conviction with them that India can economically prosper only when she is mistress in her own house, and able to carry out her own fiscal independence without any of those bonds and fetters which hitherto have circumscribed her efforts in various directions. There is the growing patriotism to work India in the interests of the Indians themselves. Such a spirit is most likely to evolve changes undreamt of hitherto. But whatever may be the changes, it is to be hoped that Lancashire will try to understand India better than it has hitherto done, in a spirit of the greatest comradeship rather than of any unhealthy rivalry; and that on the other hand India will in an equally friendly way endeavour to learn many lessons in the cotton industry which Lancashire alone is capable of teaching.

[The paper was read, in SIR DINSHAW WACHA's absence, by SIR CHARLES H. ARMSTRONG, late Chairman of the Bombay Chamber of Commerce.]

DISCUSSION.

THE CHAIRMAN (The Right Hon. E. S. Montagu, M.P.) said that the paper had given an interesting historical retrospect of the development of the cotton industry in India from ancient to modern times, but it was with the latter that practical men were primarily concerned to-day. Everyone knew that cotton, like most other things, had always presented controversial questions, and while he had no complaint against the comments that Sir Dinshaw had made on Government action in the past as a subject of legitimate controversy, it would be understood that he took no responsibility for the author's opinions. As one who had long been engaged in political controversies, there were many points on which he would be prepared to take up the challenge, but he proposed to leave that task to others whose practical acquaintance with the cotton industry was greater than his. Only a few days ago there was published as a Parliamentary paper the report of Sir Henry Birchenough's Committee on the Textile Trades after the War, and no doubt many of the audience had read that section of the report which dealt with cotton. The Committee was gravely concerned with the future of cotton supplies, and regarded it as eminently unsatisfactory that one of the principal industries of the United Kingdom should be so largely dependent upon one source of supply, and that a source entirely beyond its control. They regarded it as reasonably certain that all cotton required by the British Empire could in time be grown in its own territories, and of all sources of supply, actual or potential, they regarded India as offering the most promising prospects of any considerable increase of output within a reasonably short time. It might be that, in so far as the supply of long-stapled cotton was concerned, India might fail to satisfy in full these expectations, but that the yield of cotton per acre in India could be increased seemed beyond doubt, and it was also, he hoped, reasonably certain that if the proper measures were taken she could become a more important source of supply of long-stapled cotton than at present, and that the cultivator might be able to look forward to an adequate price for his superior cotton. It was satisfactory that the Government of India, when they received the report of Sir Henry Birchenough's Committee, immediately took the matter up in earnest, and appointed last year a committee to inquire into the whole question. The committee, which was presided over by Mr. MacKenna, Agricultural Adviser, and which included technical experts in India, Mr. Wadia, of Bombay, and Mr. Hodgkinson, of Blackburn, was about to submit its report to the Government of India, if that had not already been done, and it was to be hoped that it had been able to recommend practical measures to secure the object in view. As a producer of cotton, India occupied the most important position in the Empire, and everything possible must be done to secure and improve that position. In this respect, at all events, the interests of India and Lancashire were not antagonistic, and the Government of India had appointed a representative of Lancashire to the committee. The association of Lancashire in an Indian inquiry of that kind could not fail to be beneficial to both sides and it was not too much to hope that each might thereby have been enabled better to appreciate the needs and difficulties of the other. Not the least interesting portion of Sir Dinshaw's paper was his description of the changes in the Indian cotton industry that had been brought about by the war. In one respect the effect of the war had been of special interest. The supply of British-made goods having fallen off, owing to shipping difficulties and other causes, it was necessary to fall back on the Indian mills for Army supplies, and it was gratifying that the cotton textiles required for Army purposes were now being manufactured entirely in India. The quantities were large: for instance, to meet the requirements of a year, 20 million yards of khaki drill, 3½ million yards of khaki drill shirting, and 17½ million yards of khaki puggarree cloth had to be provided. Six large modern mills were wholly occupied in making materials for tents, and even

the khaki dyes used were now obtained, to an increasing extent, from Indian resources. That had given a tremendous fillip to the industry, and it was to be hoped that the ground gained would not be lost when peace came. So far he had confined his remarks to the cotton industry, but he thought there was a wider lesson to be learned from the paper, for in many respects what was true of cotton could be applied to other branches of industry where India possessed natural advantages. In his recent visit to India he was greatly impressed with the demands that met him everywhere, that more should be done to encourage the manufacture in India of goods the raw materials of which were produced in India. The history of the cotton trade showed that that could be done. The war had given India many opportunities of developing its own industrial capacities. The Western nations had had to restrict the man-power that they could devote to production, owing to the need for men on sterner tasks. India, at the same time, had had to develop its own efforts in order to supply the forces in the field in Mesopotamia, East Africa, and elsewhere with equipment that could hitherto be obtained from Europe. The necessity for doing this led to the creation of the Munitions Board in India, and from what he saw of their work he was satisfied that a most important step had been taken towards fostering in India the growth of industries which she had hitherto neglected. India was most favourably placed by Nature for the growth of these industries. She produced raw materials on a vast scale; she had abundant supplies of labour; she had, too, a continually-increasing number of young men, well educated and competent to undertake the direction of industrial enterprise. The war had shown the importance of increasing by all available means the self-sufficiency of the Empire—not only of the Empire, but even its separate constituents, for conditions might arise which rendered communications difficult and impeded the free exchange of goods. Even if complete self-sufficiency was not obtainable in any particular case, there was good ground for thinking that India, whose industrial development was still backward, could, under suitable guidance, develop her powers of supplying her own needs to a very large extent. But it was not only from a national or Imperial point of view that he looked forward to the growth of industrial enterprise in India. No one who went to that country could fail to be struck by its enormous wealth of mineral resources and the vast potentialities of its forests and its agriculture and water-pressure. As communications developed there was no reason why it should not have a great industrial future. Anyone who travelled through India could not help being struck by the prevailing low standard of living among the mass of the people, to be seen partly in their appearance and partly in the character of their homes. Nothing had been more strikingly associated with the growth of industrial enterprise in the West than the advancement it brought in the material conditions in which the workers lived. The organisation of labour in modern industry helped to give the worker a status which, as had been seen at home, was not so easily attainable in agriculture. But when it was once recognised that labour had the right to decent conditions of living, to a fair amount of leisure, and to a wage adequate for the discharge of a man's responsibilities, a victory had been won from which the country derived continually increasing benefit. In India wages were low—appallingly low—so low, that a small rise in prices of food or cotton might threaten to create agrarian disturbances. It could not be right that so many should have such a precarious livelihood. If new industries could only be introduced, the status of the worker in India would be improved, and that in its turn would react on the position of the peasant. The door would thus be opened to new opportunities of life and ampler means of happiness than could be obtained under existing conditions.

Sir Charles H. Armstrong said the author was a keen controversialist and a leading citizen of Bombay. His life had been spent in the Bombay cotton-mill industry; but he had, nevertheless, found time to take a leading part in local and Imperial affairs, and was now an active and prominent member of the Imperial Legislative Council, an honour he had long deserved. He had been, the speaker thought, a little hard on Lancashire. In connection with recent legislation, it must not be forgotten, in fairness to Lancashire, that the increase of duty on cotton piece-goods from $3\frac{1}{2}$ to $7\frac{1}{2}$ per cent. was rather sprung upon manufacturers and merchants, and, as a percentage figure of the competitive trade, which was used as a strong argument in the controversy, was undoubtedly underestimated, it appeared at the time as if the matter had not been thoroughly investigated, and as if the interests of consumers had not been fully considered. He did not agree with the author that Indian-made cloth did not compete with goods from Lancashire. He admitted that the qualities were not identical, but in many respects they were nowadays very similar; and when there was an appreciable difference in price in favour of Indian-made goods, the tendency was for poor consumers and those of moderate means to buy Indian cloth in preference to goods from Lancashire. Before the war, Bombay had an advantage of from 5 to 6 per cent., and owing to recent legislation, apart altogether from the very heavy increased charges for working on this side and for freight and insurance, that advantage had increased to 10 per cent., and he could not help thinking that some part of the heavy decline referred to by the author might have been brought about by that increased difference in values. There was no special reason why Lancashire should be jealous of Bombay, nor could he see any reason why Bombay should be jealous of Lancashire; but in connection with recent legislation, and in view

also of the greatly increased cost due to the war—an increase which must to some extent continue for many years—Lancashire had made up its mind that to a very large extent it had lost a valuable bulk trade in India, and that undoubtedly in normal times would be a serious matter. In the past Lancashire had often had difficulties to contend with and had generally managed to surmount them, and he felt pretty certain that in the particular case under discussion English manufacturers would not suffer materially in the long run, for in all probability they would turn on to goods of a more expensive, and therefore of a more paying character, for which, as India increased in wealth, there would be a large and increasing demand. He thought there was ample room for both Bombay and Lancashire millowners, and the people in Bombay need not be prejudiced against their fellow-workers in this country. With reference to the author's statement that the questions of housing and primary education should be dealt with by the Government and not by the Bombay millowners, he thought that, considering the difficult conditions prevailing in Bombay, it was the duty of the Bombay millowners to provide sanitary housing for their workpeople, and it would be greatly to the advantage of both if they did so. He did not understand exactly what the author meant by saying that the Bombay Government had in recent years brought pressure to bear on millowners to provide this very necessary accommodation; but it was true that for eight or ten years the Bombay Government had been anxious that sanitary accommodation should be provided for the mill-hands in Bombay, and, with the object of inducing millowners to build sanitary quarters, the Government, through the Bombay Improvement Trust, had offered terms in connection with the acquisition of land and the erection of buildings which would certainly not involve the mills in any loss, and would, in fact, bring in a moderate return on the capital outlay. When he left India, four years ago, only two or three millowners had taken advantage of the opportunity offered, and he very much regretted that so little had been done in that connection, for, as the Bombay mills were very prosperous, they could easily undertake the work if they only had the mind to do so, and the author admitted that they did not deny a moral obligation. With regard to primary education, he thought that if the mill-hands of Bombay had more education it would be better not only for the hands themselves, but also for their employers. Lancashire recognised that it would have to face in the future the Japanese competition to which the author had referred; but he thought that the Bombay millowners also had reason to fear that competition, as seemed evident from the author's remarks on the subject. He did not approve, however, of the author's suggested remedy, namely, an export duty on the raw material with the object of hampering foreign trade. Japan was the largest foreign buyer of Indian cotton, and if that trade was checked land would undoubtedly have to be turned off cotton to a considerable extent. The cotton crop of India was a large and very valuable one; it was easily grown, and in recent years had fetched very high prices. It would be an agricultural and financial disaster if anything happened in India to bring down the price of cotton materially. He believed the argument was that consumers of Indian cloth would benefit by the lower prices at which goods would be sold, but he was not at all convinced that that would be the result. Many papers had been read before the Royal Society of Arts with the object of stimulating the growth of cotton in India, and the question had recently been under investigation by an influential committee. He was strongly in favour of a largely increased output of Indian cotton, and believed that that was possible. He agreed with the author in hoping that if the committee made practical recommendations the Government would take them up at once. The export of cotton brought immense wealth into the country, and India was helped thereby in the path of industrial development. The author apparently suggested that the management of all the Indian railways should be taken over by the State, but he thought there was some mistake about that, because only the other day he had read a summary of a speech made by Sir Dinshaw in the Imperial Legislative Council in which he strongly advocated that company management should be continued. The grievance expressed in the paper was that Indian industries were placed at a disadvantage by company-managed railways, but he did not think that was really so when everything was taken into consideration and when it was remembered that the same tariff of rates was applicable to both State and company-managed lines. Instances here and there could undoubtedly be brought forward in support of the author's contention, but in fixing railway rates a great many factors had to be taken into consideration. He could not deal on the present occasion with the question of sliding scales and telescopic rates, but the fact remained that, owing to the considerations to which he had referred, certain centres from which there was a large trade inwards and outwards naturally obtained a preference. Indian railways were only worked at a small profit, and the fixing of rates was a matter that had to be carefully considered and all circumstances had to be taken into consideration. He felt sure that those who managed the railways had the interests of India very fully at heart and that a representation on the subject would always be sympathetically considered. He was confident also that in years to come Indian industries would be given every opportunity of development. He felt that the abolition of company management would be a retrograde step, and, so far as he could gather, well-informed Indian opinion, apart from the politicians, was overwhelmingly in favour of its continuance. He hoped that as time went on Indian industries would develop, but questions affecting them must be regarded from the broadest possible standpoint,

with due regard to the welfare of producers as well as consumers and of the country generally. He felt sure there was a very bright future in store for India, and hoped that after the war she would take full advantage of her opportunities.

Sir William Barton, M.P., said that Lancashire, India and the world had the same interest in the matter under discussion, namely, that the largest possible amount of cotton should be grown. Whether it suited Lancashire or not, any grade of cotton supplied some portion of the world's needs and left for Lancashire more of the kind of cotton that it needed. It was becoming more and more evident that sufficient cotton was not at present grown in the world for the world's needs. India had not produced in the past grades of cotton suitable for Lancashire trade, and personally he was sceptical whether it ever would. The climatic and soil conditions of India were such that it was only naturally capable of producing short-staple cotton, and if it could increase its growth of that article it would be making a serious and valuable contribution to the cotton trade of the world. It would thereby relieve for Lancashire the kind of cotton which India must buy if it did not itself produce the lower grade article. When passing from the growth of cotton to the finished article, they entered into the region of controversy, and he did not think that some of the charges which had been made against Lancashire in that respect were justified. The paper would lead an unsuspecting person to think that Lancashire had been moving Parliament for some preferential treatment for its trade. On the contrary, Lancashire had always moved Parliament for the abolition of all preference to all trades. Lancashire believed that the consumers' interest was the preponderating one, and, so long as India had not Home Rule and was not responsible for its own fiscal arrangements, Lancashire said, in the name of the consumers of India, that they desired they should have the same treatment under the law as the consumers of Great Britain. It had been hinted in the paper that the motives of Lancashire were somewhat mixed, but were not also some of the motives set out in the paper very mixed? He claimed for Lancashire that what they had all along asked the Government to do for India was precisely the same thing that they had asked the Government to do for themselves. The Secretary of State was sympathetic to the views he (Sir W. Barton) had held for many years with regard to the government of India. He was a democrat, believing in self-government not only for the nearer portions of the Empire but for every portion of the Empire. He asked Indians who were present not to go away with the idea that there was any inherent conflict of interest between those engaged in the cotton industry in England and those interested in the trade in India. In the long run what was good for Indian people would be good for English people. It might be in the future that Lancashire would lose its trade in certain coarser articles, but cotton was a very big commodity, and whilst there was a low-grade cotton in India Lancashire would be able more largely to use the very high-grade cotton from Egypt. He had no doubt Lancashire would emerge triumphantly from the period of great difficulty which undoubtedly lay before it. He thought the suggestion contained in the paper of an export duty on cotton going to Japan was a most dangerous one. It was unthinkable that a discrimination should be made only against Japan, which was one of our Allies, as against all other nations. An export duty on any raw material was the most dangerous expedient upon which any government could embark.

Mr. Alfred Dickinson, M.Inst.C.E., M.I.E.E., M.I.Mech.E., Consulting Engineer, Tata Hydro Electric Power Supply Company, said it had been pointed out that better cotton was grown in Egypt than in India; this was because the land was enriched by the natural fertiliser brought down by the River Nile. In India there was an absence of natural fertilisers, and, therefore, the land was poor, but it could be enriched by means of manufactured fertilisers and made to produce long-staple cotton. Fertilisers could be made cheaply by water-power. There is plenty of water in various parts of India which could be developed for that purpose. The Government ought to give every facility to reliable firms willing to undertake the manufacture of fertilisers by water-power, or themselves take immediate action with the object of securing cheap fertilisers.

Mr. Bhupendranath Basu, Member of the Council of India, in moving a vote of thanks to Sir Dinshaw Wacha for his paper and to Sir Charles Armstrong for reading it, said that people in Bengal who were not millowners had watched the growth of prices of cotton goods in India, and the consequent hardship such growth had entailed upon the consumer. They had also watched the enormous profits which cotton-mill owners in India had made, and could not understand why there should be any objection on their part to providing suitable houses for working-people and facilities for the instruction of their children. They knew something of the conditions of the life of the poor in Bombay and the houses in which they lived and of the ravages that plague made amongst them, and under those circumstances they could not reconcile the prosperity of the cotton-mill owners with their unwillingness to contribute to the happiness and comfort of the operatives they employed. At present there was no organisation of labour in India, and probably would not be for many years; and he would like to know what increase of wages had been granted to the cotton operatives, to whom Sir Dinshaw was unwilling to grant the boon of providing sanitary dwellings, in view of the fact that they were unorganised? The owners of jute-mills in Calcutta had also made phenomenal profits during the past year, and what had they done for their operatives? How much of the

profits had gone to the owners and how little to the workmen, whose labour had enabled them to earn such large profits? For many years to come, owing to want of education amongst the poorer working-people, labour organisations and unions such as were seen in England and other European countries were not likely to grow in India, and therefore he did not see why it should not be the function of the State to come to the assistance of people who were not able to help themselves. He would not go into the vexed question of the relative merits of the dispute between Lancashire and Bombay. Indians, however, felt they had a grievance against Lancashire, their bigger brother in the industry, in its treatment of India in that respect. Personally, he did not associate himself with the imposition of an export duty on raw materials, it being a very dangerous proposition. It would ultimately mean loss to the cultivator and shrinkage of the area under cultivation. The cultivator ought to have open to him the whole of the markets of the world. Owing to war conditions jute did not have a free market; it could only be used by the millowners in Dundee and Bengal, with the result that they were able to organise and force down the price to such an extent that the growers of jute at one time seriously thought of burning their crops rather than cutting and selling them on the terms offered.

SIR FREDERICK A. ROBERTSON, K.B.E., LL.D., in seconding the motion, endorsed the Secretary of State's remarks in regard to the enormous value to India of an increase in her industries and also of finding proper channels into which the clever, educated young men of India could direct their attention in lieu of the only professions they at present sought to enter, *i.e.*, Government service or a "learned profession."

SIR HAMILTON FREER-SMITH, C.S.I. (President of the Indian Factory Labour Committee, 1906–7), in supporting the motion, said he thought that more should have been said about the welfare of the 240,000 workers in the cotton industry. The dwellings of the workers that he saw in Bombay were a disgrace to humanity and civilisation, a standing menace not only to the health of the workers, but also to the whole community. It was largely due to the petty discussion that had arisen as to who should provide proper accommodation. The time had come when the housing question should be seriously taken up, and also other questions connected with the industry, such, for instance, as slack administration of the Factory Acts, enabling half-timers to work whole time by working in two mills on the same day; excess of humidity in weaving sheds; excess of dust in certain works, and dangerous machinery.

The motion was unanimously adopted and acknowledged by Sir Charles Armstrong on behalf of Sir Dinshaw Wacha and himself.

SIR WILLIAM DUKE, G.C.I.E., K.C.S.I. (Chairman of the Indian Section Committee), in thanking the Secretary of State for presiding, said the Society knew it could always count upon Mr. Montagu's active interest in connection with any subject which was of real importance to India. The subject-matter of the paper was regarded as of somewhat special importance, while the occasion of the meeting was also of peculiar importance, so far as the Society was concerned, from a sentimental point of view, because the present meeting completed the fiftieth annual session of the Indian Section of the Royal Society of Arts. The Society was, therefore, all the more grateful to the Secretary of State for having honoured it by his presence on such an occasion.

The resolution having been carried by acclamation, the CHAIRMAN assured the Society that it had been a very great pleasure to him to be present, and he desired heartily to congratulate the Indian Section upon attaining its jubilee.

MR. D. T. CHADWICK, I.C.S. (Indian Trade Commissioner), who would have spoken at the meeting if time had permitted, writes:—Sir Dinshaw Wacha, in his most excellent summary, touched on most of the problems connected with cotton in India. Others spoke on the attitude of Lancashire and the condition of the Bombay operative, but one point so far was not mentioned, viz., the raw cotton, which is really the base of the industry. It is clear that there has been a great increase in the quantity of cotton produced, but I feel that Sir Dinshaw gives a somewhat pessimistic account of the conditions and prospects of this cultivation. It is true that the yield per acre is considerably less than in the United States and Egypt, but the Egyptian crop is primarily an irrigated one, whilst that of India is mainly a rain-fed crop. Even so I should not like it to go forth that 66 lb. is a normal yield per acre in India. The figures quoted are those for the current year, which was notoriously unfavourable to the cotton crop in our largest cotton areas, viz., the Central Provinces, Hyderabad, and Bombay. The average normal yield is from 85 to 90 lb. Sir Dinshaw does not anticipate much improvement in quantity and quality until the financial position of the ryot has been improved, and elementary agricultural education becomes general, but improvements are not waiting upon the realisation of such efforts. Much has been done, and is being done, in the selection and distribution of better seed, in the organisation of selling and marketing, in the testing of new varieties, and in the selling and distribution of new agricultural machinery. Thus, in the Central Provinces alone, over 800,000 acres were, in 1916–17, cultivated with a particular type of cotton which had been obtained by selection, and which had given at experimental stations over a period of seven years an average yield of 204 lb. of lint per acre as compared with the normal yield of a little over 100. This has meant an increased

profit of over 120 lakhs a year to the farmers in that Province alone. In the Punjab over 200,000 acres have been sown with a long-staple variety of heavier yield, more profitable than previous kinds in both quality and quantity. In South Madras a very similar result has been obtained on a very similar scale, whereby ryots are getting a premium of 16 rupees per 500 lb. on account of the superior quality and purity of the cotton. Moreover, in the south, Cambodia—a stamp of cotton when delivered pure well suited for Lancashire—has been introduced and is being grown extensively. There is as good Cambodia available as was ever grown, and most of the best is procured by local mills. These are merely cited as far-flung illustrations of work in progress everywhere.

Thus, whilst I am in full agreement with Sir Dinshaw that much work remains to be done—for the total area under cotton in India runs from twenty to twenty-five million acres—yet results that have recently been obtained hold out promise that with steady work, and above all with surety of a good market, much could be effected both in increasing the yield and in the improvement of quality of Indian cotton, and from such advance Indian mills should be the first to reap the benefit. India is vastly nearer such achievements than she was fifty years ago. The improvements effected are not restricted purely to seed, but also extend to the use of new implements and better methods of cultivation. Thus again, purely for illustration, the Bombay Agricultural Department last year sold direct to cultivators machinery worth 92,000 rupees. It is, therefore, natural that the recommendations of the Indian Cotton Committee are being awaited with much interest, in the hope that they will give direction to future effort and advice as to the lines which can most profitably be followed.

One of the main difficulties which has so far faced the agricultural reformer is not the impossibility of growing a better article, but the difficulty of ensuring that the full reward of such improvement reaches the cultivator. Without the stimulus of price and the surety of his market it is unreasonable to expect any farmer to venture more capital on his cultivation, or to risk new methods except, perhaps, under the fear of absolute extinction. It has been truly said that high manuring is no remedy for low prices. Thus, when at last these changes are beginning to take effect, and ryots in many parts are beginning to get some of the extra profits due to them for better cultivation and greater care, it is disturbing to hear that certain thinkers—I do not quite gather that Sir Dinshaw endorses this contention—contemplate a restriction of the ryots' market, even resulting in a decrease of the area cultivated and of total production which would, of course, result from a narrow market and a low price. Nothing would be more likely to throw back the small improvements already obtained, and to check further progress, as the uncertainty which would then take the place of that confidence which ryots have now learnt to repose in cotton. It is easy to say that the place of cotton could be taken by some other marketable crop, but in much of the land on which cotton is cultivated cotton is the main money crop to the farmer, and the land, climate and agricultural conditions do not often permit of others being substituted. Such an economic loss to the cultivators of one of our most important staples would have a far wider and more serious effect than the assessment which is put forward as one of the chief causes of the ryots' penury, of which, by the way, recent examinations of registered agricultural leases in ryotwari parts of Madras showed the assessment was about one-sixth of what the landlord takes as rent. I refer to lands temporarily settled and not held under permanent settlements. Agriculturists in India in their work towards the improvement of local crops have derived, generally speaking, most valuable help and advice from the local industries where such are established in India. This has notably been the case in cotton, and had there been no local mills to help with advice, make tests of samples and give enhanced prices for better grades, there could not have been so much agricultural progress to report as at present there is.

As others dealt with trade matters I have confined myself purely to agriculture, and as an agriculturist can say that a better balance between industry and agriculture in India will be all to the benefit of Indian agriculturists.

Mr. E. C. de Segundo, Assoc.M.Inst.C.E., writes:—One of the most important of the many important results brought about by this terrible world-conflict is the spirit which has been awakened throughout the length and breadth of the Empire, and is operating to consolidate the Empire in a degree exceeding, I venture to think, the most sanguine dreams of the most ardent Imperialists in pre-war days. The valuable and interesting paper of Sir Dinshaw E. Wacha deals with one factor in this process of consolidation, namely, the relative positions of India as a cotton-growing country, and Lancashire as a great market for raw cotton. For reasons which will, no doubt, be well known to many readers, it may be said, without fear of contradiction, that India offers the best prospect of relieving the anomalous position of Lancashire in regard to its supplies of raw cotton, and it is important to note that within the last few years the cultivation of the American variety of cotton in India has progressed in a very satisfactory manner, the production having now reached (during 1917) the equivalent of 400,000 bales of 500 lb., a quantity which, however, is but a small proportion of that which Lancashire usually draws annually from the United States.

In Lancashire, Indian cotton has a bad name, and no doubt spinners have had ample justification for the prejudice they have formed. It must be remembered, however, that it is only within recent years that any serious attention has been given to the science of cotton cultivation, and that spinners themselves are unable to specify the physical characteristics of the cotton they require. The

painstaking research work on cotton cultivation carried out in Egypt by Dr. Lawrence Balls—which, unhappily, was interrupted in 1913, and is not, apparently, to be resumed—gave indication of most valuable results in the direction of bridging the gap between grower and spinner. The expert opinions expressed by such authorities as Mr. D. T. Chadwick, Professor John A. Todd, Dr. Lawrence Balls, and others, leave no doubt as to the practicability of a vast improvement in the methods of cultivation of cotton in India, and in the conditions under which it is brought to market, which would result in a material improvement in the length of staple, the quality of cotton, and the yield per acre.

Sir Dinshaw has touched upon the future of India as an integral part of the Empire, a question which cannot fail gravely to preoccupy the minds of all interested in the welfare of the Empire as a whole. The India of to-day is not what it was when it first came under British rule. We could not think much of the efficiency of British rule if it were. Many instances can now be cited of commercial and industrial development in India, due to the enterprise and great business ability of Indian firms. The evolution of India has reached a stage at which there is danger on the one hand of the parent country failing to realise that the child country is growing up, and, on the other, that the child country, chafing under the restrictive effect of parental authority, may be led prematurely to endeavour to free itself from its leading-strings, and thus, in its inexperience, get rid of the ills it knows only to fly to others it knows not of. We must be under no illusion that this war is going to end war, and the safety of the British Empire, with which the safety of India is indissolubly bound up, demands that the component parts of the Empire be so welded together as to become a self-supporting whole under conditions admitting of the abundance of one part supplying the want of another, to the end that "there may be an equality," as was advised by St. Paul, on general principles, some nineteen hundred years ago. No sane person can to-day fail to discern the meaning of the "handwriting on the wall," and to realise that the storm centre is moving eastwards. It will be the part of wisdom for India to see to it that in concentrating her attention upon internal development and economic position, she is not merely adding to her value as a prize for some nation whose natural resources are already developed up to the hilt, and who is seeking, and must find, fresh fields and pastures new for her surplus population and for the exercise of her industrial activities.

OBITUARY.

Edward Adolphus Victor Abraham.—Mr. Edward A. V. Abraham, who had been a Fellow of the Royal Society of Arts since 1912, died at his residence in Georgetown, British Guiana, on June 4th.

Mr. Abraham was born at Georgetown in 1852, and educated at Queen's College. In 1882 he was created a Notary Public, and five years later was admitted by the Supreme Court as a solicitor. In addition to his extensive legal practice, he undertook a great deal of public work. He was Mayor of Georgetown for the years 1903–5; he served on various commissions, on the Tuberculosis Executive, and the Board of Agriculture, and he was more than once Financial Representative. Besides this, he was a sportsman of the most catholic taste, and took a deep interest in shooting, rowing, cycling, racing, cricket, gymnastics: at one time he even organised a meeting for goat races.

Henry Charles Stephens.—By the death of Mr. Henry Charles Stephens the Society loses a Fellow whose name has figured in its books since 1867. He was born in 1841, and educated at University College, London. He became the senior partner in the firm of ink manufacturers which bears his name, and he was also well known as an agriculturist and breeder of pedigree stock. He represented the Hornsey Division as a Unionist from 1887–1900.

GENERAL NOTES.

Industrial Establishments in India.—Figures recently published by the Department of Statistics in India show that in the year 1915 there were in that country 4,053 industrial establishments, employing in the aggregate 1,335,147 persons. Of the total establishments, 171 were owned by Government, local bodies, or State *darbars*; and 3,882 by companies or individuals. For the leading industries—cotton, jute, etc.—the particulars are given separately. Industries employing less than 5,000 persons are included under "others." The industries in the latter category number 649, with nearly 100,000 hands. Cotton-mills and cotton-ginning and pressing factories combined employed upwards of 400,000 persons. The 72 jute mills, 69 of which are in Bengal and the remaining three in Madras, came next with 250,764 operatives. In addition, 26,305 were working in jute presses. Tanneries and leather works, of which there were 41, had 9,339 employees.

Hydro-Electric Projects in Australia.—According to H.M. Trade Commissioner in Melbourne, it has been decided by the Victorian Government that before undertaking the development of the brown coal deposits, to which considerable attention has been devoted, for the supply of electrical energy, an investigation should be made as to the possibility of utilising the water-powers of the State for the same purpose. The Tasmanian Minister of Mines is reported to have stated that he does not anticipate any difficulty in financing the development of water-power on the King River at a cost of £1,000,000. It is estimated that 45,000 h.p. can be developed on this river.

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

REPORT ON THE "OWEN JONES" PRIZES.

Following the precedent of 1917, the Council this year, with the kind assistance of the Director of the Victoria and Albert Museum, arranged for a competition of students of Schools of Art in accordance with the terms of the Owen Jones Trust. Notices were issued in November last stating that six prizes would be offered under the usual conditions. Each prize consists of a bound copy of Owen Jones's "Leading Principles in Composition of Ornament" and a Bronze Medal. The competition this year was limited to Designs for (1) Chintzes, and other Stamped, Printed, or Stencilled Textile Materials; (2) Wallpapers; and (3) Tiles. The date for the receipt of competing designs was fixed for June 29th, 1918, and arrangements were made for their inspection at the Victoria and Albert Museum.

The following judges were appointed by the Council to consider the designs submitted: Mr. Alan S. Cole, C.B., Professor W. R. Lethaby, Mr. T. C. Moore, Mr. John Slater, F.R.I.B.A., Sir Frank Warner, K.B.E., and Mr. Arthur Wilcock.

Thirty-seven designs or works were sent in from nine Schools of Art by thirty-one students. The judges report that these numbers are small when compared with those of last year, when one hundred and twenty designs or works were sent in from twenty-two Schools of Art by seventy-three students. The falling off of numbers is attributed partly to war conditions, which are even more strenuous than they were a year ago; and partly to the subjects prescribed for the competition, which are perhaps less attractive than those set in 1917.

The general standard of the work is good, although somewhat uneven, some designs showing quite matured, others very elementary ability. The judges are gratified to find that, generally, greater care has been paid to the technical requirements of the process for which the design is intended, as was suggested by them last year. While they would again insist on this technical quality, it must be understood that it alone would not secure an award where the artistic quality is low.

The awards of the judges are as follows:—

PRIZES.

Almenrader, Dorothy M., School of Art, Hornsey, N.
Design for block-printed Wallpaper filling in fourteen colours.

Bulley, Mary A., L.C.C. School of Art, Putney, S.W.
Two Sheets of Designs for Ceiling papers.

Froom, Dorothy M., School of Art, Hornsey, N.
Design for a block-printed Cretonne in ten colours.

Goodale, Winifred, L.C.C. School of Art, Putney, S.W.
Design for repeating Tile—with Tiles (unfired).

Phillips, Margery L., L.C.C. School of Art, Putney, S.W.
Design for Encaustic Tiles for floor covering.

COMMENDED.

Berry, Ivy A., School of Art, Hornsey, N.
Design for block-printed Wallpaper in sixteen colours.

Goodale, Winifred, L.C.C. School of Art, Putney, S.W.
Design for printed Cretonne to be executed in nine colours.

Grierson, Edith, Municipal School of Art, Manchester.
Design for Printed Textile.

Hammond, Bertram, School of Art, Macclesfield.
Design for Printed Cretonne.

Hodgson, Gladys, School of Art, Hornsey, N.
Design for block-printed Taffeta in eight colours.

Kipling, Arthur W., School of Art, Glossop.
Design for printed Cotton fabric in nine colours.

Tippin, Alice Bertha, City School of Art, Hope Street, Liverpool.
Design for Stencilled Tablecloth with Stencil and preliminary drawing.

Arrangements have been made for the exhibition to the public of the competing designs. They will be on view from July 20th to August 31st, from 10 a.m. to 6 p.m. in the Class Room, Department of Textiles (First Floor), Victoria and Albert Museum, South Kensington, S.W.

In announcing the awards the Council desire to add an expression of their thanks to the judges for the trouble they have devoted to the work and for the promptitude with which the awards have been made.

They wish also to state their appreciation of the assistance rendered to the Society by the Director of the Victoria and Albert Museum and his staff.

The conditions and arrangements for the Competition in 1919 will be announced later.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE EFFECT OF THE WAR ON THE ECONOMIC CONDITION OF THE UNITED KINGDOM.

By Edgar Crammond,

Late Secretary of the Liverpool Stock Exchange; Managing Director of B.S.T. Limited.

Lecture I.—Delivered February 18th, 1918.

It is proposed to discuss the effect of the war upon the economic condition of the United Kingdom, and to offer some observations with regard to the real cost of the war, the problem of economic reconstruction, and our trade policy after the war. The scope of the inquiry is very wide, and it is not practicable to deal with every aspect of the question in great detail.

It will not be possible to pass final judgment upon many of the economic problems which the war has created until a considerable time after the conclusion of peace, but if we are to pursue an intelligent and reasoned policy in relation to our post-war economic problems, we cannot afford to wait until, say, ten years after peace. We must form our conclusions now in the light of the facts as we understand them to-day and the experience which we have obtained during the past three years and a half.

The war marks a close of an old economic epoch and the opening of a new era, and in order to attain a full appreciation of the changes which the war has brought about, it is necessary to consider first the economic position of the United Kingdom before July, 1914.

The question will be considered under three main headings, viz.:—

1. The economic condition of the United Kingdom before the war;
2. The economic condition of the United Kingdom after three and a half years of war;
3. The real cost of the war, the problem of economic reconstruction and trade after the war.

The first question to which attention may be directed is that of population. The table given below shows the growth of population in the United Kingdom since 1821, and relative proportions of each division of the United Kingdom.

The increase of population in the United Kingdom in the inter-censal periods since 1881 was as follows:—

1881–1891	8·2 per cent.
1891–1901	9·9 ,,
1901–1911	9·1 ,,

Between 1881–1911 the population of the United Kingdom increased from 34,884,848 to 45,216,665. Between 1880–1910 the population of the German Empire increased from 45,234,061 to 64,925,993, the increases for the three inter-censal periods being:—

1880–1890	9·3 per cent.
1890–1900	14·0 ,,
1900–1910	15·2 ,,

Census of Population.

Census of	Population of United Kingdom.	Population of England and Wales.	Per cent. of U.K.	Population of Ireland.	Per cent. of U.K.	Population of Scotland.	Per cent. of U.K.
1821	20,893,584	12,000,236	57·4	6,801,827	32·6	3,091,521	10·0
1831	24,028,584	14,156,988	57·9	7,767,401	32·3	2,364,386	9·8
1841	26,730,929	15,914,148	59·5	8,196,597	30·7	2,620,184	9·8

1871	31,484,661	22,712,266	72·1	5,412,377	17·2	3,360,018	10·7
1881	34,884,848	25,974,439	74·5	5,174,836	14·8	3,735,573	10·7
1891	37,732,922	29,002,525	76·8	4,704,750	12·5	4,025,647	10·7
1901	41,458,721	32,527,843	78·4	4,458,775	10·8	4,472,103	10·8
1911	45,216,665	36,075,269	79·8	4,381,951	9·7	4,759,445	10·5

In the ten years 1901–1911 the death-rate of the United Kingdom dropped to 15·7 per thousand, compared with 18·2 for the previous inter-censal period. At the census of 1901 the population of the United Kingdom was 41,458,721, and at that in 1911 it was 45,216,665, the increase between 1901 and 1911 being 3,757,944. The number of births recorded in the inter-censal period was 11,614,000; the number of deaths, 6,771,000, the natural increase thus amounting to 4,843,000. The difference between this figure and the actual recorded increase in the population, viz., 1,086,000, was accounted for by migration, which has, of course, exercised a very marked influence upon the growth of population in the United Kingdom. The Board of Trade figures show that during the inter-censal period emigration amounted to 1,350,000, so that there remains a difference of 264,000 between the census results and the actual recorded emigration. This difference was in part due to the fact that there was a war in South Africa during the decade, and consequently a large movement of troops to and from South Africa, and it is estimated that between 160,000 and 200,000 returning troops were not included in the Board of Trade returns because they arrived on troopships. Between 1901–1911, 336,000 people, or 100 per cent. of its natural increase, emigrated from Ireland. Scotland had a natural increase in population of 51,791 in 1910, but the passengers leaving Scottish ports numbered 55,344 in the same year.

It is instructive to note the nationality and the destinations of emigrants. The English provided 63 per cent., the Scottish 20 per cent., the Irish 13 per cent., the Welsh 1 per cent., and the Colonials 3 per cent. of the total of the 397,000 emigrants gross outwards in 1910. In the past twenty years there was a remarkable change in the destinations of emigrants. In the period 1891–1900, 28 per cent. of the emigrants went to the Dominions and 72 per cent. to foreign countries. In 1900, 33 per cent. went to the Dominions and 67 per cent. to foreign countries. In 1910, 68 per cent. went to the Dominions and 32 per cent. to foreign countries. In 1911, 80 per cent. went to the Dominions and 20 per cent. to foreign countries.

The migration of women has been considerably less than that of men, and the average for the whole forty years has been less than 22 per cent. of the total natural increase of the female population. In the forty years from 1871–1911, 590,000 more males than females emigrated from England and Wales alone. This is the main reason for the great excess of females in England and Wales. In 1871 the excess of females over males was 594,000; in 1881, 694,000; in 1891, 896,000; in 1901, 1,070,000; and in 1911 it rose to 1,179,000. It is instructive to note that, on the other hand, there is a notable deficiency of females in some of the Colonies. In Canada in 1911 there were 437,000 fewer females than males; in New Zealand 55,000 less females, and in Australia 171,000 less females than males.

It is necessary now to consider the occupations and the production of the people of the United Kingdom. The census for 1911 showed that there were 35,748,000 persons, occupied and unoccupied, aged ten years and upwards. Of this total, 2,886,000 males and 12,704,000 females were returned as retired or unoccupied, leaving 14,307,000 males and 5,851,000 females occupied. The returns made under the Census of Production Act give a fairly comprehensive view of the production and principal industries of the United Kingdom in the year 1907. They show that the gross value of the output of the 7,250,000 persons who came within the scope of the Act was £1,765,366,000, and the net output, that is the value of the work done, was £712,135,000. It is estimated that if complete returns had been received with regard to all the persons coming within the scope of the Act the net qutput would have been valued at £762,000,000. The results of the Census of Production, so far as they relate to the industries dealt with in the Census of Production Office, are shown in the table, "Census of Production," given on page 568.

One of the most surprising features of the Production Report was the small number of persons engaged in production and the comparative smallness of the output. The question of distribution is evidently one of great importance. Special inquiry should be directed to this matter. We seem to have had too many persons occupied in distribution and too few occupied in production.

It will be observed that, while the Census of Population gave a total of occupied persons amounting to 20,158,000, the Census of Production only covered the activities of about 8½ million persons. The agricultural output was obtained by the Board of Agriculture and Fisheries, and the Department of Agriculture and Technical Instruction for Ireland, which undertook a voluntary census of agriculture for the year ending June 4th, 1908. The following

CENSUS OF PRODUCTION.

GROUP OF TRADES.	GROSS OUTPUT. Selling Value or Value of Work done.			Average Number of Persons Employed (excluding Outworkers).		
	England and Wales.	Scotland.	Ireland.	England and Wales.	Scotland.	Ireland.
	£	£	£			
Mines and Quarries	125,151,000	22,617,000	258,000	829,371	132,096	3,763
Iron and Steel, Engineering and Shipbuilding Trades	307,809,000	61,573,000	5,814,000	1,270,913	230,691	37,811
Metal Trades, other than Iron and Steel	91,493,000	1,790,000	182,000	108,138	5,555	780
Textiles, except "Other Cotton Manufactures"	279,565,000	29,154,000	15,836,000	984,813	141,184	92,355

Clothing Trades	94,056,000	8,737,000	5,190,000	638,159	75,899	42,408
Food and Drink Trades	205,177,000	31,064,000	27,335,000	319,502	70,968	35,583
Tobacco Trade*		[23,870,000*]			[37,648*]	
Chemical and Allied Trades (except Explosives and Ammunition)	63,303,000	6,591,000	1,191,000	103,238	9,274	2,586
Explosives and Ammunition*		[3,947,000*]			[12,744*]	
Paper, Printing, Stationery and Allied Trades	50,845,000	8,771,000	1,692,000	268,476	44.440	12,559
Leather and Canvas Trades	22,849,000	2,945,000	226,000	53,473	6,208	1,004
India-rubber Trade*		[8,908,000*]			[24,039*]	
Timber Trades (except "House Furnishings not of Wood")	31,418,000	7,590,000	1,279,000	180,848	34,480	7,706
"House Furnishings not of Wood"*		[6,103,000*]			[16,161*]	
Clay, Stone, Building and Contracting Trades	101,443,000	12,831,000	2,418,000	626,138	80,557	18,545
Miscellaneous Trades	7,615,000	599,000	74,000	42,584	3,940	350
Public Utility Services	67,538,000	6,609,000	2,904,000	280,673	29,395	32,423
Factory Owners—Power only	—	—	—	806	—	—
Total	1,490,749,000	207,840,000	66,777,000	5,808,269	885,403	291,304

* In the case of these trades separate particulars for the several divisions of the United Kingdom are not given in order to avoid possible disclosures of information relating to certain firms. In the total figures for all trades for England and Wales, for Scotland, and for Ireland separately, a distribution of these amounts and numbers has been included.

table sets forth the particulars contained in the reports of those bodies:—

	Agricultural Produce.	Number of Persons employed.
	£	
England and Wales	127,650,000	*1,128,000
Scotland	23,150,000	212,000
Ireland	45,574,000	†984,000
Total	196,374,000	2,324,000

Particulars as to fisheries are as under:—

	Value of Fish landed.	Persons employed. Regularly.	Occasionally.
	£		
England & Wales	8,156,000	36,210	7,464
Scotland	3,221,000	28,951	10,366
Ireland	341,000	8,027	16,405
Total	11,718,000	73,188	34,235

* England and Wales—persons employed, excluding occupiers numbering about 500,000 in Great Britain.

† Ireland—persons employed, including farmers.

There are consequently 2,931,000 persons engaged in agriculture and fishing, and the total output was approximately £208,000,000. In considering this total, it should be observed that it excludes the value of dairy produce and cider consumed by farmers' households in Great Britain, the output of farm, market garden and fruit crops from holdings not exceeding one acre, and certain other produce; but it appears not unreasonable to estimate the value of the total agricultural and garden output and fisheries at about £222,000,000.

The question of the national food supply before the war has been carefully studied by the Food (War Committee) of the Royal Society, and their conclusions are embodied in Command Paper 8421. It was found necessary to convert the total food consumed to a common basis. "For this purpose it was necessary to select some unit of measurement which is common to all foods. Observations have shown that the human being derives his power of work from the oxidation of his food, which in this respect is comparable to the fuel of a steam

TABLE V.

SUMMARY OF FOOD SUPPLY OF UNITED KINGDOM.

Average of five years, 1909 to 1913 inclusive.

	Weight in Metric tons.			Work-producing Power in Millions of calories.		
	Home Grown.	Imported.	Total.	Home Grown.	Imported.	Total.
Cereals	1,010,000	3,855,000	4,865,000	3,705,000	14,007,000	17,712,000
Meat	1,615,000	1,070,000	2,685,000	5,369,000	3,521,000	8,890,000
Poultry and eggs, game and rabbits	170,000	161,000	331,000	235,000	226,000	461,000
Fish	715,500	132,900	848,400	392,000	139,000	531,000
Dairy produce (including lard and margarine)	4,704,000	527,800	5,231,800	4,715,000	3,538,000	8,253,000
Fruit	341,000	930,000	1,271,000	168,000	909,000	1,077,000
Potatoes and other vegetables	4,788,000	694,000	5,482,000	4,054,000	758,000	4,812,000
Sugar (including cocoa and chocolate)	—	1,657,000	1,657,000	—	6,633,000	6,633,000
Cottage and farm produce not included above	—	—	—	2,655,000	—	2,655,000
Totals	—	—	—	21,293,000	29,731,000	51,024,000

engine or motor car. The work-producing power of coal, oil, or petrol is measured in calories, or units of heat. This unit is the most convenient measure for the work-producing power of foods. A full consideration of the dietary requirements of a nation for the most part engaged in active work has convinced the Committee that these requirements cannot be satisfactorily met on a less supply in the foods purchased than 100 grammes protein, 100 grammes fat, 500 grammes carbo-hydrates, equal approximately to between 3,400 calories per man per day—a man being an average workman doing an average day's work. The population of the United Kingdom was taken as 45·2 millions. Generally speaking, a woman or child requires less food than a man. To afford the population of men, women, and children the net units per man as defined above, the total number must be reduced by 23 per cent. The quantities of foodstuffs available during the period 1909–13 were:—

	Protein. Grammes.	Fat. Grammes.	Carbo-hydrates. Grammes.	Calories.
Per head	87	100	440	3,091
Per man	113	130	571	5,009

The supply, therefore, not only met our requirements in the past, but also provided a margin of 600 calories per man, or 15 per cent.

With regard to the question as to the proportion of food that was home grown, the investigations of the Committee referred to showed that out of 51,000,000 calories consumed, 29,700,000 calories, or 58·2 per cent., were imported, and only 21,300,000 calories, or 41·8 per cent., were home grown (see Table V.). This does not quite agree with the returns made under the Census of Production, which indicated that the value of imported foodstuffs was £244·7 millions, and the home grown food production of £205·3 millions; that is, the imports represented 45·2 per cent. of the value of the food consumed, and the home grown proportion was 45·8 per cent.

The interdependence of the United Kingdom on foreign trade is one of the most striking features of the Census of Production Report. The value of the raw materials produced in the United Kingdom was £149·6 millions, of which total coal represented £114·6 millions. The value of the exports of raw materials was £43·5 millions, leaving the home consumption of raw materials produced in the United Kingdom £106·1 millions. The value of the net imports of raw materials was £192·1 millions, so that in 1907 the total consumption of raw materials was £298·2 millions, of which £192·1 millions, or 64·4 per cent., were obtained from abroad and 35·6 per cent. were produced at home. It will be observed, therefore, that we are even more dependent upon foreign supplies of raw materials than we are upon foreign supplies of food.

The returns made under the Census of Production enable us to frame some conclusion as to the amount of the national income and the manner in which it is spent; and after a careful and detailed examination of these returns, together with the figures relating to our foreign

trade contained in the Statistical Abstract, I have prepared the following estimate of the national income and national expenditure for the year 1907:—

FOOD.

(Millions of £)

	Home Production.	Imports.	Exports.	Estimated Home Consumption.
Wheat and Flour	10·6	44·0	0·6	54·0
Potatoes	11·7	—	—	11·7
Vegetables	11·6	5·2	0·4	16·4
Meat	83·5	51·9	1·7	133·7
Fish	11·7	2·9	1·5	13·1
Milk	28·4	—	—	28·4
Butter and Margarine	9·6	25·4	0·4	34·6
Cheese	1·4	6·9	0·2	8·1
Eggs and Poultry	10·3	7·1	—	17·4
Lard	—	4·9	0·1	4·8
Fruit (including Dried Fruit imported and Spices)	5·6	15·1	1·2	19·5
Sugar (deduct 10 per cent. for quantity used in brewing and distilling, and add allowance for refining at home)	—	20·7	0·7	20·0
Tea (plus one-seventh for landing and warehousing)	—	10·9	2·1	8·8
Coffee	—	2·4	1·3	1·1
Cocoa (plus one-seventh for landing and warehousing)	—	3·0	0·5	2·5 0·5
				374·6

DRINK AND TOBACCO.

	Home Production.	Imports.	Exports.	Estimated Home Consumption.
Beer	67·2	—	1·9	65·3
Spirits	8·8	—	3·1	5·7
Brandy and Liqueurs	—	1·8	0·2	1·6
Wine (plus one-eighth for landing and warehousing)	—	4·4	0·5	3·9
Tobacco	23·9	4·2	1·4	26·7
Aerated Waters	6·0	—	0·6	5·4
				108·6
Total Food, Drink and Tobacco				483·2

DRESS.

	Home Production.	Imports.	Exports.	Estimated Home Consumption.
Cotton Manufactures	174·6	9·8	113·5	70·9
Woollen Manufactures	75·9	10·8	34·8	51·9
Linen	18·6	1·6	7·0	13·2
Silk	5·2	13·4	4·4	14·2
Leather (including Boots, Shoes and Gloves)	41·4	12·7	8·2	45·9
Diamonds	—	8·8	0·3	8·5
Lace	—	1·6	—	1·6
Feathers	—	2·5	1·2	1·3
Miscellaneous (including Perfumery)	—	—	—	3·6
Net output of clothing, handkerchief and millinery trades	64·7	—	—	64·7
Laundry and cleaning	9·4	—	—	9·4
				285·2
Deduct estimated proportion of Home Consumption of Cotton, Woollen, Linen and Leather Manufactures used for other purposes than Dress				37·0
				248·2

HOUSE.

	Home Production.	Imports.	Exports.	Estimated Home Consumption.
House Rent (from House Duty Returns)	—	—	—	150·0
Furniture and Miscellaneous	18·1	12·3	12·0	18·4
China, Glass and Earthenware	7·6	1·0	4·2	4·4
Coal (34,000,000 tons at £1 per ton)	—	—	—	34·0
Gas—				
Companies	20·8			
Public Authorities	10·8	Less estimated proportion used in manufacturing, etc., industries		28·5
Electric Light—				
Companies	3·2			
Public Authorities	5·7			
Water—				
Companies	2·2			
Public Authorities	8·5	do.		10·7
				246·0

NATIONAL SERVICES, 1907-8.

Army and Navy	58·0
Post Office	18·0
Civil List and Civil Administration (less education)	19·0
Local Government Services (less education, gas, water and other items)	89·0
Total	184·0

MISCELLANEOUS.

Education (including Parliamentary grants and local rates)	40·0
Literature	23·0
Newspapers	14·0
Church (including 14·0 for revenues of Church of England, with estimates for Scotland and Ireland, and for dissent)	25·0
Locomotion—	
Tramways— Companies 4·5, Public Authorities 9·3	13·8
Half receipts from Railway passengers	25·5
Motoring	20·0
Theatres and Amusements	25·0
Total	186·3

The cost of distribution is, of course, a very formidable item in the national expenditure, and with regard to this matter the final report states :—

"The accounts of the English Co-operative Wholesale Society show that the expenses of their wholesale business range from 1½ per cent. on purchases in the case of grocery (where the transactions are on a very large scale) to 5 or 8 per cent. in the case of other goods. The Wholesale Society does not work for a commercial profit. Examination of the accounts of a considerable number of large distributive co-operative societies, working in competitive districts, shows that profits and expenses together run between 20 and 35 per cent. of the cost of purchases, from 8 to 12 per cent. representing expenses. Inquiries made by the Census of Production Office regarding ordinary retail trade show that when allowance is made for certain cases where the sum required to cover retailers' expenses and profits may fall as low as 10 per cent. of the cost of the goods to the retailer, and for other cases where that sum may rise above 50 or even 100 per cent. of the cost, an addition of from 25 to 40 per cent. to the cost of goods to the retailer will, for the great bulk of trade, express the range within which the expenses and profits of retailers lie."

The following is a summary of the national expenditure for the year 1907, on the basis of the figures quoted above :—

	Amount. (Million £)	Percentage of total income.
Food, Drink and Tobacco	483·2	22·4
Dress	248·2	11·5
House	246·0	11·4
National Services	184·0	8·5
Miscellaneous	186·3	8·6
Professional and Domestic Services not comprised in above items	100·0	4·6
Cost of Distribution	200·0	9·3
	1,647·7	
Depreciation and Maintenance of Capital	180·0	8·3
New Investments at home	150·0	7·4
New Investments abroad	176·0	8·0
	2,153·7	100·0

Thus, before the war, food, clothes, rent, the cost of distribution and miscellaneous services absorbed about 67·8 per cent. of the national income. National Services only called for 8·5 per cent.; depreciation, 8·3 per cent.; while 15·4 per cent. was saved—the latter item being fairly evenly divided between new investments at home and new investments abroad.

The income tax returns confirm the estimate of the national income arrived at on the basis of the Census of Production returns. The rule of thumb method of estimating the aggregate income is to double the gross assessment to income tax. For the year to March, 1909, the gross income reviewed by the several bodies of Income Tax Commissioners amounted to £1,009,935,926; and, applying the method indicated above, we arrive at an aggregate income of about £2,020,000,000.

Shipping, including its allied trades, constitutes our premier industry; and I have prepared the following table to show the total

number of persons engaged, and the aggregate capital employed:—*

	Approximate number of persons employed.	Approximate amount of capital employed. £
Shipping	300,000†	600,000,000
Shipbuilding	210,000	150,000,000
Port and Harbour Authorities	60,000	140,000,000
Miscellaneous (including dock labourers, warehousemen, shipping clerks, underwriters, etc.)	260,000	100,000,000
	830,000	£990,000,000

If we include the persons employed in fishing and the peace establishment of the Royal Navy, it will be found that the total number of persons directly employed in connection with our shipping exceeds 1,000,000.

It is now necessary to consider the growth of our foreign trade. During the ten years which preceded the outbreak of war, there was a remarkable development of the foreign trade of the United Kingdom. The nature and extent of the expansion in shown in the following table:—

Imports.	(Million £) 1904.	1913.	Increase per cent.
Food	219·7	274·3	24·8
Raw Materials (other than Coal)	143·0	217·8	52·3
Manufactured Articles	115·9	164·1	41·6
Re-exports (Transit Trade)	70·3	109·5	55·8
Miscellaneous	2·1	3·0	42·0
	551·0	768·7	39·5

Exports.	(Million £) 1904.	1913.	Increase per cent.
Food	16·7	32·6	93·2
Raw Materials (other than Coal)	9·3	16·2	73·4
Manufactured Articles	243·3	411·4	69·0
Coal	26·8	53·6	99·7
Re-exports	70·3	109·6	55·8
Miscellaneous	4·6	11·4	166·0
	371·0	634·8	71·1

In 1904, the value of the imports exceeded the value of the exports by £180 millions, whereas in 1913 the excess of imports was only £133·9 millions. This was due to the fact that the exports increased at a much more rapid rate than the imports. Of course, in 1904 we were beginning to recover from the effects of the South African War, and we had resumed the investment of capital abroad, which had been interrupted during the war. The investment of capital abroad has exercised a very great influence upon the expansion and direction of British trade.

Exports and Investments.—The Board of Trade returns for the past thirty years, together with the data available as to the investment of capital abroad, establish in the clearest manner the absolute dependence of our exports of commodities upon the amount of capital lent to our foreign and colonial debtors. Between 1880 and 1890, we lent money on a liberal scale to the United States, Argentina, and Australasia. In fact, we lent too freely, and without discrimination. During the decade, the total amount invested abroad was about £600,000,000, or at the rate of £60,000,000 per annum. Now, in 1880 the exports of United Kingdom produce were valued at £223,000,000; and in 1890, at £263,000,000, thus showing an increase during the eleven years of £40,000,000. In the early nineties our foreign investments began to show heavy losses. These were in part due to the shrinkage in the value of our investments in Brazil and Argentina, owing to the revolutionary troubles in those countries, and to the Baring crisis, which followed in 1890. Then the passing of the Sherman Silver Act in the United States was followed by a commercial and financial crisis, which caused several bank failures; and many of the American railways passed into the hands of receivers. The closing of the Indian Mints, in 1893, depreciated the value of our investments in all silver countries, and the same year witnessed an acute financial crisis in Australia. These unfavourable events, and the heavy losses which they entailed, naturally made a profound impression upon the mind of the British investor, and the total amount invested abroad during the decade 1890–1900 was only £250,000,000, or at the rate of £25,000,000 per annum. The effect of this contraction of credit upon our exports was immediate and unmistakable. Our exports of United Kingdom produce, valued at £263,000,000 in 1890, fell to £216,000,000 in 1894, and by 1899 they had recovered only to £255,000,000, or £8,000,000 less than the total at which they were valued in 1890. It is also instructive to note that during the period when our investments abroad were on a very small scale, there was a huge appreciation in the market value of home securities.

The drastic measures taken by British investors compelled our foreign and colonial debtors to place their finances in a sound position, to live within their income, and to develop their natural resources in the most

* The British Shipping Industry.

† Including 31,000 foreigners and 51,000 Lascars.

economical and efficient manner possible; and by the end of 1899 our foreign investments were beginning to yield a largely increased income. Our imports amounted to £421,000,000 in 1890, when our exports of United Kingdom produce were valued at £263,000,000; whereas, in 1899, when our exports of United Kingdom produce were valued at only £255,000,000, our imports were £485,000,000, and there is no evidence whatever to show that during that time we were selling our investments abroad. Towards the end of the decade the confidence of British investors in foreign investments was, therefore, beginning to revive; and there was a marked tendency to resume the outflow of capital on a considerable scale when the South African War broke out. The losses and expenses caused by this conflict resulted in a partial suspension of the investment of capital abroad for two or three years. But during the war there was a world-wide improvement in trade, due in part to a succession of good crops in the United States, Canada, and Argentina, as well as to the reaction after the universal depression of 1890–1899, with the result that our foreign investments not only became very remunerative, but greatly improved in value. As soon, therefore, as the wastage and cost of the war ceased, British capital was available for investment abroad on a very large scale, and from 1904 onwards it was poured out by this country at an unprecedented rate, with the result that there was a tremendous increase in the value of our exports of manufacture.

Income from Investments Abroad. — The amount of income which the Commissioners of Inland Revenue were able to earmark as derived from colonial and foreign investments in the year ended April 5th, 1914, was £118,113,703, made up of £9,206,703 from Indian Government stocks, loans, and guaranteed railways; £27,766,323 from colonial and foreign Government securities, and £80,640,677 from colonial and foreign securities other than Government. But these items form only part of the total income which accrues to this country in respect of its foreign and colonial investments, for they do not include: (*a*) Concerns (other than railways) situated abroad, but having their seat of direction and management in this country—*e.g.* mines, gasworks, waterworks, tramways, breweries, tea and coffee plantations, nitrate grounds, oilfields, land and financial companies; (*b*) concerns jointly worked abroad and in this country, such as electric telegraph cables and shipping; (*c*) foreign and colonial branches of banks, insurance companies, and mercantile houses in the United Kingdom; (*d*) mortgages of property and other loans and deposits abroad belonging to banks, insurance companies, land, mortgage, and financial companies, etc., in this country; and (*e*) profits of all kinds arising from business done abroad by manufacturers, merchants, and commission agents resident in the United Kingdom. There is ground for the belief that the income derived from the sources which are not earmarked by the Commissioners of Inland Revenue approximates to that of the identified income; but if the unidentified income is assumed to equal only 80 per cent. of the identified income, it amounts to at least £95,000,000. The total income from foreign and colonial investments would thus be well over £200,000,000 per annum, which, capitalised on the basis of twenty years' purchase, represents an aggregate capital sum of £4,000,000,000.

Capital Invested.—Confirmation of this estimate is afforded by a detailed examination of the amount of British capital invested in each of our Overseas Dominions and Possessions, and in each foreign country. The following summary indicates the approximate distribution of our foreign and colonial investments in millions of pounds at the end of 1913, together with the comparative figures for 1896:—

British Dominions, Colonies and Possessions.	1896.	1913.	Increase.
India (including Ceylon)	294	447	153
Australia and New Zealand	323	408	85
Africa	333	401	68
Canada	140	423	283
Other British Possessions	33	91	58
Total	1,123	1,770	647
Foreign Countries.			
United States	315	632	317
Argentina	117	329	212
Brazil	45	135	90
Mexico	27	81	54
Japan	13	74	61
Chile	29	57	28
Egypt	51	75	24
Uruguay	23	40	17
China	26	38	12
Peru	21	32	11
Cuba	5	29	24
European Countries	254	170	84*
Other foreign countries	43	92	49
Total	969	1,784	815
Grand total, British Dominions and foreign countries	2,092	3,554	1,462

This aggregate of £3,554,000,000 comprises only the capital invested in colonial or foreign

* Decrease.

loans or in public undertakings or companies, and it does not include any provision for the very large amounts of capital privately invested abroad in the purchase of land, etc., nor the capital employed abroad by the principal British banking, mercantile, and shipping houses. If it be assumed that these private investments are equivalent to 10 per cent. of the public investments—a very moderate estimate—a further sum of £350,000,000 must be added to the total, making the aggregate value of all British investments abroad £4,000,000,000, a total which approximates to that arrived at on the basis of the capitalisation of the estimated income at 5 per cent.

Geographical Distribution.—It will be observed that the total of the investments has been fairly evenly divided between the Overseas Dominions and the rest of the world, and that the British investor has taken good care not to place all his eggs in one basket. The moiety invested in the Empire has been almost equally distributed among the three great Dominions and our greatest Dependency, and although upwards of £600,000,000 of British capital was placed in the United States, the remainder of the moiety invested in foreign countries was very well spread. In the early years our principal investments were made in Europe, but as the European countries developed and the yield became less remunerative, it was perceived that Canada, Australia, Argentina, Chile, and other distant countries offered a more profitable field. France, and to a lesser degree Germany, invested their surplus accumulations of capital largely in Russia, Turkey, Austria, the Balkan States, and other parts of Europe. Great Britain, on the other hand, pursued a bolder policy, one which was largely influenced by her shipping, and she has no reason just now to regret having invested her savings in the development of countries which are in the main remote from Europe.

The great bulk of the capital invested abroad by Great Britain has been applied to the construction of railways, irrigation works, waterworks, and harbours, or to the development of mines, nitrate fields, tea, coffee and rubber plantations, oilfields, etc.—in short, to every conceivable form of enterprise calculated to increase the world's supplies of food and raw materials. This increase of productiveness has not been conducted on selfish lines. The additional supplies of food and raw materials have been made accessible to the whole world; and it is difficult to believe that the industrial development of Germany during the past twenty years would have been possible had it not been for the enterprise and ability of British investors. The value of British investments abroad increased during the seventeen years, 1896–1913, by the enormous sum of £1,462,000,000, or at the average rate of £86,000,000 per annum. The decrease of £84,000,000 in the value of our investments in Europe is noteworthy.

We are now in a position to examine the manner in which our trade balance was adjusted before the war. I believe it is not yet generally appreciated that the value of our exports as shown in the Board of Trade returns is "f.o.b.," that is, free on board, and the value of the imports is "c.i.f.," that is, cost, insurance and freight. As we carry, insure and finance three-fourths of our own trade, and at least one-half of the sea-borne commerce of the world, it is obvious that the real position of our trade balance is very much better than would appear by merely considering the values of the imports and exports. The following estimate gives the approximate figures for 1912, so far as I have been able to calculate them.*

UNITED KINGDOM, YEAR 1912.

Credits.

	£
Exports of domestic produce, etc.	487,434,000
Re-exports	111,838,000
Exports of bullion and specie	64,871,000
Invisible Exports—	
Interest on investments abroad	185,000,000
Proportion of gross earnings of British mercantile marine brought home, say	100,000,000
Gross earnings of British banking, mercantile, commission and insurance houses carrying on trade abroad	55,000,000
Total	£1,004,143,000

Debits.

	£
Imports—	
Commodities	444,897,000
Bullion and specie	76,311,000
Invisible Imports—	
Amount of capital invested abroad	185,000,000
Interest payable on foreign and colonial holdings of British securities, and earnings of foreign and colonial banks, insurance companies, etc., carrying on British business within the U.K.	20,000,000
Total	£1,026,208,000

It is out of the question to submit a statement which will show an exact balance, because there are so many items which enter into the

* "Economic Relations of the British and German Empires," *Journal of the Royal Statistical Society*, June, 1914.

adjustment of the trade balance for which no reliable data are available. The above table does not include the value of the fish landed at British ports during the year 1912, which amounted to £13,234,000, nor does it include the imports and exports of precious stones (the average value of the net imports cannot be less than £4,000,000 per annum). Again, it is impossible to frame estimates of the amount annually expended abroad by British tourists or the earnings of British subjects abroad which are annually remitted home to this country. In this connection it is interesting to note that the pensions payable in England by the Indian Government alone exceed £2,000,000 per annum. It is equally difficult to frame an estimate of the amount annually expended in the United Kingdom by foreign tourists, or the earnings of foreigners resident in this country which are annually remitted abroad. On the whole, it may be assumed that these two groups of income and expenditure set off each other.

Before the war the national finances were in an eminently sound condition. Almost alone amongst the Great Powers we were steadily reducing the amount of the National Debt. At the end of the South African War it stood at £798,000,000; by the end of 1913 we had got it down to £707,000,000—or say, about 4½ per cent. of the estimated national wealth.

The revenue of the Imperial Government for the year to March 31st, 1914, was £198,000,000 —or, say, about 9 per cent. of the national income—and was derived from the following sources:—

	£
Customs	35,450,000
Excise	39,590,000
Estate Duties	27,359,000
Stamps	9,966,000
House Duty, etc.	3,415,000
Income Tax, etc.	47,249,000
	£163,029,000
Non-Tax Revenue (principally Post Office)	35,214,000
	£198,243,000

The expenditure in the Army amounted to £28,346,000 and the Navy to £48,833,000, while the National Debt charge absorbed £24,500,000.

In 1913–14 the total amount of indirect taxation was £69,000,000, and it represented 42 per cent. of the tax revenue; the direct taxation was £93,000,000, and it represented 57 per cent. of the tax revenue.

In view of the demands which have been put forward for the institution of a Federal form of government for Ireland and Scotland, the question of the fairness of the incidence of Imperial taxation is one of very great importance, and the following tables show the result of investigations carried out by the writer in 1911–12 in order to determine the relative taxable capacity of each division of the United Kingdom:—

ESTIMATED TAXABLE CAPACITY OF ENGLAND AND WALES.*

	United Kingdom.	England and Wales.	England and Wales' percentage of U.K.
Population (census of 1911)	45,216,665	36,075,269	79·8
	£	£	
Gross assessments to income tax (1909–10)	1,011,100,344	877,888,486	86·8
Net capital of estates liable to estate duty (1910–11)	272,724,000	229,701,000	84·2
Estimated national wealth (1909)	15,882,464,000	13,716,779,000	86·4
Estimated national income (1909)	1,998,000,000	1,741,000,000	87·2
Foreign trade (1910)	1,327,225,000	1,107,709,000	83·5
Estimated net production returned under Census of Production Act, 1907 (including agricultural production and sea fisheries)	919,500,000	738,700,000	80·3

The average of the above indices is 84·03.

* "England's Economic Position and her Financial Relations with Scotland and Ireland."

ESTIMATED TAXABLE CAPACITY OF SCOTLAND.†

	United Kingdom.	Scotland.	Scotland's percentage of U.K.
Population (census of 1911)	45,216,665	4,759,445	10·5
	£	£	
Gross assessments to income tax (1909–10)	1,011,100,344	93,020,031	9·2
Net capital of estates liable to estate duty (1910–11)	272,724,000	28,313,000	10·4
Estimated national wealth (1909)	15,882,464,000	1,451,625,000	9·1
Estimated national income (1909)	1,998,000,000	174,000,000	8·7
Foreign trade (1910)	1,327,225,000	88,628,000	6·6
Estimated net production returned under Census of Production Act, 1907 (including agricultural production and sea fisheries)	919,500,000	113,300,000	12·3

The average of the above indices is 9·54.

† "The Economic Position of Scotland and her Financial Relations with England and Ireland."

ESTIMATED TAXABLE CAPACITY OF IRELAND.*

	United Kingdom.	Ireland.	Ireland's percentage of U.K.
Population (census of 1911)	45,216,665	4,381,951	9·7
	£	£	
Gross assessments to income tax (1909–10). . .	1,011,100,344	40,191,827	4·0
Net capital of estates liable to estate duty (1910–11)	272,724,000	14,710,000	5·4
Estimated national wealth (1909)	15,882,464,000	714,060,000	4·5
Estimated national income (1909)	1,998,000,000	83,000,000	4·1
Foreign or external trade (1910)	1,327,225,000	130,888,000	9·9
Estimated net production returned under Census of Production Act, 1907 (including agricultural production and sea fisheries).	919,500,000	67,500,000	7·4

The average of the above indices is 6·43 per cent. It is submitted that the average ratio in each table fairly represents the taxable capacity of the country concerned in relation to the United Kingdom as a whole.

* "Ireland's Part in the War," *Nineteenth Century and After*, May, 1917.

It will be observed from the data submitted above, that before the war the taxable capacity of England and Wales, in relation to the United Kingdom as a whole, was 84·03 per cent.; that of Scotland, 9·54 per cent.; and that of Ireland, 6·43 per cent. It is instructive to compare these figures with the total revenue, local expenditure and contribution towards Imperial expenditure from England and Wales, Scotland, and Ireland during each of the years ending March 31st, 1914 and 1917, which details are furnished below:—

	England and Wales.	Per cent.	Scotland.	Per cent.	Ireland.	Per cent.	Total.
YEAR TO MARCH 31ST, 1914.							
	£		£		£		£
Total revenue as contributed	162,491,000	83·36	21,309,500	10·93	11,134,500	5·71	194,935,000
Local expenditure . . .	66,659,500	74·80	10,105,000	11·34	12,357,000	13·86	89,121,500
Revenue contributed in excess of local expenditure .	95,831,500	—	11,204,500	—	—	—	—
Local expenditure in excess of revenue contributed .	—	—	—	—	1,222,500	—	—
Net balance available for Imperial expenditure . .	—	—	—	—	—	—	105,813,500
YEAR TO MARCH 31ST, 1917.							
Total revenue as contributed	464,255,500	84·41	61,978,000	11·27	23,766,500	4·32	550,000,000
Local expenditure . . .	66,834,000	74·86	9,763,500	10·93	12,686,000	14·21	89,283,500
Contribution towards Imperial expenditure . .	397,421,500	86·26	52,214,500	11·33	11,080,500	2·41	460,716,500

contributed by each division of the United Kingdom approximated very closely to that obtained in the year before the war, and this proves the fairness of incidence as well as the elasticity of our unitary fiscal system—a fairness and elasticity which it would be almost impossible to attain under a federal system of finance.

With regard to the expenditure upon local services, it will be noted that, while Ireland's contribution to the revenue in 1914 was only 5·71 per cent. of the total, her share of the

The above tables show that in 1914 England and Wales, with an estimated taxable capacity of 84·03 per cent., contributed 83·36 per cent. of the total revenue; Scotland, with a taxable capacity of 9·54 per cent., contributed 10·93 per cent. of the revenue; and Ireland, with a taxable capacity of 6·43 per cent., contributed 5·71 per cent. of the revenue. Notwithstanding the disturbance of the fiscal system, caused by the vast increase of £355,000,000 in the amount of revenue raised in the year to March 31st, 1917, we find that England contributed 84·41 per cent. of the revenue; Scotland, 11·27 per cent.; and Ireland, 4·32 per cent. The percentage

local expenditure was no less than 13·86 per cent. For the year 1917 Ireland's share of the revenue was 4·32 per cent., and her share of the local expenditure was 14·21 per cent. It will be observed, therefore, that Ireland's expenditure is altogether disproportionate to her revenue.

With regard to the amount contributed towards the cost of Imperial services by each division of the United Kingdom, it may be pointed out that England and Wales increased their amount from £95,831,500 to £397,421,500; Scotland increased her amount from £11,204,500 to £52,214,500; while Ireland turned a deficit

of £1,222,500 into a surplus of £11,080,500. Although this latter sum was a great improvement, it only represented 2·41 per cent. of the total contributed by the United Kingdom for Imperial services. Had Ireland's contribution been proportionate to her taxable capacity—*i.e.* 6·43 per cent.—she would have provided for the year to March 31st, 1917, a sum of about £27,000,000, instead of only £11,080,500.

It has been persistently claimed by the protagonists of Home Rule that Ireland is overtaxed. This claim cannot be sustained. Before the war Ireland did not contribute to the revenue proportionately to her income and resources. The whole tendency of war taxation is to place the burden more and more upon the direct taxpayer, and this falls much more heavily upon England and Scotland than it does upon Ireland. Again, Ireland receives twice as large a share of the local expenditure of the United Kingdom as she is entitled to on the basis of her contribution to revenue.

Summaring the conclusions arrived at above, it may be said that during the forty-four years of intensive economic development which preceded the outbreak of war, Great Britain, in common with the other leading industrial States of the world, had been accumulating immense reserves of economic strength. We had a population in the United Kingdom of 45·2 millions, together with 15 million people of the British race in the Overseas Dominions and Possessions. The total population of the Empire was 449 millions. Our merchant fleet amounted to over 20 million tons gross, only about one-half of that tonnage being employed in the carrying trade of the United Kingdom. The national wealth of the United Kingdom was about £16,500 millions, and the national income £2,140 millions.*

The national wealth of the Overseas Dominions and Possessions was £9,504 millions and the national income £1,346 millions,† making the total wealth of the Empire £26,000 millions and the total income £3,486 millions.

The United Kingdom's share of the international trade of the world was 15·9 per cent. and the Overseas Dominions and Possessions' share was 12·7 per cent., so that the British Empire transacted 28·6 per cent. of the trade of the whole world. The steam-power equipment of our industries amounted to over 10,755,000 horse-power, and our output of coal was 280 million tons per annum. Our investments abroad were valued at £4,000 millions, and they brought us an annual income of £200 millions. The manner in which these resources were converted to purposes of the war will be discussed in my second lecture.

* "Economic Relations of the British and German Empires," *Journal of the Royal Statistical Society*, July, 1914.

† "Imperial Defence and Finance," *Nineteenth Century and After*, August, 1913.

ENGINEERING NOTES.

Electric Welding as a Substitute for Riveting.—This is being tested by the United States Government at four shipbuilding yards, and so far the work is proving highly satisfactory. According to recent data, the process will increase the strength of the joint at least 25 per cent., and decrease the time of building a hull nearly 50 per cent. Eminent engineers claim that there will be a saving in labour of 60 to 70 per cent. The machine employed is the Wilson welder. At present, the plates are being lap-welded, the plates being overlapped at least two inches, sometimes more, and each edge welded down. In the future, it is the intention to butt-weld the plates (a great economy in weight, and hence in tonnage as well as in workmanship) in a manner described in an article in the *Marine Review* of May last. No reheating nor annealing is necessary. Thirty welders can do the work of 125 riveters. The Wilson welding outfit operates on what is known as the arc principle, and consists of a motor generator set, the generator of which is wound for thirty-five volts. The welding metal serves as one electrode, while the ship-plates constitute the other electrode.

Gearless Electric Locomotive for the Chicago, Milwaukee and St. Paul Railway.—A paper describing this engine, read by Mr. A. H. Armstrong, before the New York Railroad Club, states that the excellent operating results obtained during the past ten years with gearless motor locomotives on the New York Central lines have attracted increasing attention to this form of construction. The extreme simplicity in design offered by mounting the armature directly upon the driving axle, thus eliminating all gears, quills, rack-shafts, side rods, etc., has been reflected in the great reliability and low cost of maintenance. It is, therefore, an achievement of much importance to announce the entry of the gearless locomotive in the mountain grade haulage, as it can be reasonably expected that this type of construction holds promise of equally good operation in the heaviest class of railway road service. The gearless locomotive for the Chicago, Milwaukee and St. Paul extension to Seattle is equipped with fourteen axles, twelve of which are drivers and two guiding axles. The armature is mounted directly upon the axle and, with the wheels, constitutes the only dead or non-spring-borne weight of the locomotive. This weight

is approximately 9,500 lb., as compared with 17,000 lb. deadweight on the driving axles of the present geared locomotives now in operation on the Chicago, Milwaukee and St. Paul railway.

The Macchi Single-seater Fighting Aeroplane.—This is one of the most efficient flying-boats ever built, says *Aircraft*. Owing to the fineness of its construction, its light weight, and high-powered motor, it is able to ascend to an altitude of 13,000 ft. in only eighteen minutes. In a single-seater fighting machine, quick climbing power is, of course, one of the important essentials of performance, although this adaptability to climbing rapidly is not generally associated with machines of the flying-boat class. Head resistance has been reduced to a minimum, especially in regard to the inter-plane bracing. The struts and interplane bracing are similar in principle to that employed in the French Nieuport Scout—the single pairs of V struts, the narrow lower plane, and the outline of the planes themselves bear a resemblance to the Nieuport. The Macchi is provided with steel tube overhung braces, because of the area extending beyond the interplane struts. The overall dimensions of the machine are:—Span 39 ft. $4\frac{7}{16}$ in.; overall length, 27 ft. 3 in.; overall height, 9 ft. $10\frac{1}{16}$ in. There is a lifting surface of 301 sq. ft. The loading per square foot is 6·85 lb. When empty the machine weighs 1,510 lb., when fully loaded to its gross weight, 2,060 lb. There are two Fiat machine-guns, both firing forward. The engine is an Isotta-Frascini 150 h.p. The loading of the machine is 11·8 lb. per brake horse-power. It is known as the V.4B. This is a six-cylinder vertical type, with a nominal horse-power of 150, and at bench-test horse-power of 190 at 1,400 revolutions per minute. Bore, 5·2 in.; stroke, 7·1 in.; overall dimensions of the V.4B.; length, 5 ft. $0\frac{15}{16}$ in., height, 3 ft. $3\frac{1}{8}$ in.; width, 2 ft. $3\frac{15}{16}$ in. Carburettors, zenith; magneto, Marelli. The weight of the engine complete, dry, is 573 lb. Its weight per brake horse-power is 3·01 lb. Petrol is consumed at the rate of 92·6 lb. per hour; consumption per brake horse-power 7·4 oz.

The Utilisation of the Douro Falls.—The *Sol* announces the formation of a powerful company to exploit these falls, which form the frontier between Spain and Portugal. They are 300 ft. high, and are reckoned to be capable of developing 350,000 h.p., more than sufficient to supply the present annual shortage of coal, amounting to about 2,000,000 tons. The capital of the company is entirely Spanish, and amounts to £6,000,000, the greater part of which is controlled by the Banco de Bilbao. The power thus developed will be conducted to Madrid, Bilbao, and throughout Galicia, and will thus affect a large part of the Peninsula. The enterprise is expected to hasten the electrification of the railways throughout the north and east of Spain, and bring about an industrial development that will enrich the country to an incalculable degree.

Hydro-electric Power in France.—According to the *Génie Civil*, Commander H. Cohen, at the civil engineers' congress held recently in Paris, spoke on the considerable *rôle* played by water-power in war time, and said that some important results had been obtained. Before the war 750,000 h.p. with a realisable value of 800 million francs was made use of, this being about one-tenth of the total power available, which is estimated to be at least about 8 million h.p. In Switzerland, official statistics published in 1914 prove that the water-power used there is 16 per cent. of the available total. In August 1915, a start was made to intensify the resources of water-power, and manufacturers made, at the request of the Under-Secretary for War Materials, great efforts in spite of many difficulties. Since the end of 1915, the falls which had been, or were in course of development, represented at least 565,000 h.p., and those actually in harness represented 850,000 h.p. Further, at the end of 1917, 120,000 h.p. were placed at the disposal of the National Defence; 330,000 h.p. were harnessed in 1918, and the remainder will be completed during 1919 and 1920. By the end of 1921, France will have, at least 1,600,000 h.p. under control, representing a value of 1,500 million francs.

GENERAL NOTE.

THE RAW COTTON PROBLEM.—In an article which Sir Charles W. Macara contributes to the *Textile Review*, he urges the cotton industry to take in hand at once the question of establishing a reserve of cotton. The price of raw cotton has soared to an almost incredible height, and the stocks available for the mills are being greatly depleted. He fears a crisis is again arising. Any surplus that may have been grown as a consequence of the exceptional prices ruling during the past two years, and that will be accumulated as a result of the enforced idleness of so many spindles and looms owing to war conditions, should be controlled by the Governments concerned. He also insists upon the urgent need for improved baling for the American crop. It has been demonstrated that, by increasing the density of packing, millions of pounds sterling would be saved yearly. The Egyptian gin-compressed bale is, he says, the best on the market, and he strongly recommends American growers to adopt that type of bale, "not in the remote future, but now."

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

FRIDAY, AUGUST 2, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

INDIAN SECTION.

A meeting of the Indian Section Committee was held on Monday, July 29th. Present:—

Sir William Duke, G.C.I.E, K.C.S.I. (Chairman of the Committee), in the chair; T. J. Bennett, C.I.E.; Sir M. M. Bhownaggree, K.C.I.E.; Sir Valentine Chirol; Sir Frederic W. R. Fryer, K.C.S.I.; Sir H. Evan M. James, K.C.I.E., C.S.I.; Colonel Sir A. Henry McMahon, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I.: Sir Prabashankar Dalpatram Pattani, K.C.I.E.; N. C. Sen, O.B.E.; J. A. Voelcker, M.A., Ph.D., F.I.C.; Sir Frank Warner, K.B.E.; and Colonel C. E. Yate, C.S.I., C.M.G., M.P.; with G. K. Menzies, M.A. (Secretary of the Society), and S. Digby, C.I.E. (Secretary of the Section).

LECTURES ON "THE FREEDOM OF THE SEA."

The Special Lectures on "The Freedom of the Sea," delivered before the Society in May last, have been printed in pamphlet form. The pamphlet contains three lectures: I.—The Freedom of the Seas, by Gerard Fiennes; II.—The Freedom of the Sea in War, by Sir Francis Piggott; III.—The German "Freedom of the Sea," by John Leyland; and a summary of the course, by Admiral Sir Edmond T. W. Slade, K.C.I.E., K.C.V.O.

Copies of the pamphlet (price 1*s.* 6*d.*) may be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. (2)

EXAMINATIONS.

The results of the Intermediate (Stage II.) Examinations, held from May 6th-15th last, were sent to the centres concerned on July 29th.

It is hoped to send out the results of the Elementary Stage about the middle of August.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE ECONOMIC CONDITION OF THE UNITED KINGDOM AFTER THREE AND A HALF YEARS OF WAR.

By EDGAR CRAMMOND,
Late Secretary of the Liverpool Stock Exchange; Managing Director of B.S.T. Limited.

Lecture II.—Delivered February 25th, 1918.

In my previous lecture I gave a summary of the economic conditions of the United Kingdom immediately before the outbreak of war. It is now proposed to outline as briefly as possible the principal economic changes which occurred during the first three and a half crowded years of the war. There is not sufficient time available, nor is it necessary for the purposes of our survey, to furnish a detailed historical statement of all the economic events, and I must content myself with a brief account of the most important changes and the manner in which they were brought about.

The Empire entered upon the war with almost immeasurable reserves of economic power, but, owing to our neglect of the problem of financial preparation for war and the contempt of our people and politicians for statistics, these vast resources were utterly unorganised. The task before our Government and the nation was, first, to survey and organise the national resources; secondly, to enrol and equip an army on the Continental standard; thirdly, to transform the entire fabric of our economic life, with all its international complexities and ramifications, from peace production to war production; fourthly, to increase the output of commodities on the new basis necessitated by the war; and, fifthly, to convert the resources accumulated through three

centuries of commercial intercourse with the world into war munitions or war services.

Before the war, out of a total national income of £2,153 millions, only £77 millions, or 3·5 per cent., were allocated for the purposes of the Army and Navy. By the end of the third year of war it had become necessary to allocate for the purposes of the war £2,700 millions. As a matter of fact, part of this amount was borrowed abroad, but the United Kingdom in 1917 provided about £1,800 millions, or, say, 51 per cent. of the increased national income for the purpose of carrying on the war. The Overseas Dominions were faced with the same problem of converting their national resources from peace production to war production.

Many people have expressed a feeling of despair at the slowness with which we applied our full strength to the purposes of the war, but they do not appear to have realised the complexity—the overwhelming magnitude—of the task, and particularly the interaction of international influences on our economic life. To have instantly mobilised the whole nation on a war basis without feeling the way and providing the organisation would probably have impaired our economic strength and weakened the British staying power—the surest foundation of complete victory.

About the end of July, 1914, there were over 2,500 large British merchant ships on the high seas. Our foreign trade was running at the rate of £1,400 millions per annum. British bills for the conduct of the international trade of the world were in circulation to the value of between £400 and £500 millions. Stock Exchange loans to the extent of £90 millions were in existence, and the gold reserves at the Bank of England stood at only £38 millions. A great war, involving two-thirds of the peoples of the world, crashed into this delicate and complicated machinery, and the result was chaos for a brief period. Happily, the Government realised the magnitude of the crisis and the fact that it could only be dealt with adequately by hypothecating the credit of the country. The emergency legislation which was rushed through, notwithstanding the imperfections due to hurried drafting, proved sound, and met, to a large extent, the needs of the situation. The inherent strength of our credit system rapidly manifested itself. Our vast credits in foreign countries were called in, and during the first five months of the war our gold reserve increased from £27 millions (to which it fell on August 5th, 1914) to £69 millions on December 31st, 1914. Happily, the greatest source of our national strength, viz. our sea power, was ready, and our Navy and our merchant fleet were immediately mobilised for war. The British Navy at once took the command of the sea and kept it clear for the British mercantile marine to fulfil its vital functions.

The failure of the German armies to reach Paris and the destruction of the German naval forces in the Falkland Islands battle restored confidence, and by the end of 1914 the United Kingdom had overcome the first shock of the war and settled down to the task of organising its economic life on a war footing. The temper of the people was magnificent; workers and employers hastened to settle their outstanding differences, and an industrial truce was proclaimed which for various reasons only lasted until the early part of 1915. In 1914 there were 999 disputes, involving 448,000 workpeople and a loss of 10,111,000 working days. In 1915 there were 674 disputes, involving 446,000 workpeople and a loss of only 2,969,000 working days. In 1916 there were disputes involving 284,000 workpeople and a loss of 2,599,000 working days; and in 1917 there were disputes involving 820,000 workpeople and a loss of 5,513,000 working days. Volunteers flocked to the colours in hundreds of thousands, and by the end of 1915 no less than two and a half millions had joined the Army or Navy voluntarily, and an equally large number had, under the attestation scheme, expressed their readiness to join. On May 25th, 1916, His Majesty issued a message expressing his recognition of the splendid patriotism and self-sacrifice displayed by his people by the voluntary enlistment of no less than 5,041,000 men since the commencement of the war. It was found impracticable to continue the voluntary principle after May, 1916, and compulsory service was then instituted.

On October 27th, 1917, Lord Curzon said the total tonnage of the Navy in 1914 was 4 million tons; it was then 6 million tons. Of the mercantile marine over 3,300 vessels were engaged as mine-sweepers or patrols.

On January 14th, 1918, Sir Auckland Geddes stated that in August, 1914, the total *personnel* of the Navy was less than 150,000. The Regular Army, including Reserves and Special Reserves, amounted on mobilisation to about 450,000 men. The Territorial Force contributed some 250,000 more. Of one sort or another, therefore, there were available 700,000 soldiers. The Navy,

from 150,000 in August, 1914, stood in October, 1917, at 400,000. "The British Army to-day has on its rolls over 4,000,000 men. The actual strength of the forces to-day obviously only represents a part of the call that has been made upon our man power; to it must be added our losses . . . the effort which the British nations have made under the one item of 'Provision of men for the Armed Forces of the Crown' amounts to not less than 7,500,000. Of these, 4,530,000, or 60·4 per cent., have been contributed by England; 620,000, or 8·3 per cent., have been contributed by Scotland; 280,000, or 3·7 per cent., have been contributed by Wales; 170,000, or 2·3 per cent., have been contributed by Ireland; and 900,000, or 12 per cent., have been contributed by the Dominions and the Colonies. The remaining million men, composed of native fighting troops, labour corps, carriers, etc., represent the splendid contributions made by India and our various African and other dependencies."

The war had a very marked effect on the marriage rate in England and Wales. For 1909–13, the average number of marriages was 274,725; 1914, 294,401; 1915, 360,885; and 1916, 279,846. For the first two quarters of 1917, the returns showed heavy decreases as compared with 1915 and 1916, and they indicate that the total for 1917 will be considerably below the average for 1909–13.

The births in England and Wales declined from 881,890 in 1913 to 814,614 in 1915 and 785,520 in 1916. There was a decrease in 1915 of 7·6 per cent. on 1913, and in 1916 a decrease of 10·9 per cent. on 1913, and for the first three quarters of 1917 a decrease of 23 per cent. on 1913.

In Scotland the decrease was relatively smaller, but still very substantial.

**Death Rate.*—The following is a statement of the deaths in the civil population only for the years 1913–17:—

	England and Wales.	Scotland.	Ireland.	United Kingdom.
1913	504,975	73,069	74,694	652,738
1914	516,742	73,557	71,345	661,644
1915	553,476	81,157	76,151	710,784
1916	499,145	70,642	71,391	641,178
1917 (1st half)	291,561	—	—	—

The main feature of this table is the rise in the death rate in 1915, followed by a heavy fall in 1916, and a large rise again in the first half of 1917.

Excess of Births over Deaths.—During the period from July, 1914, to June, 1917, the excess of births over deaths for the United Kingdom was 904,000. *"This excess is very considerably greater than the total loss of lives by English, Welsh, Scotch and Irish soldiers and sailors during the period of the war. Migration, which in normal years plays an important part in determining the increase or decrease in the population, has, during the war, ceased to such an extent as to make its influence of comparatively little account. As a matter of fact there is a small balance of gain to the United Kingdom from this source, amounting for the period in question to 115,000 persons of both sexes and all nationalities. The gain is generally due to the migration of Belgian refugees."

After six months of war, it became apparent that the arrangements for the supply of munitions were wholly inadequate, and that, in order to obtain a sufficient output and to provide equipment for the new armies, it would be necessary to mobilise the whole of the industrial resources of the nation; and on June 25th, 1915, the Ministry of Munitions was created. The Act provided that there should be no strike or lock-out at works engaged in the supply of munitions; that any disputes must be referred to arbitration; that there should be Government control of workshops and Munition Courts would have power to inflict penalties; that trade union regulations restricting output should be suspended and employers' profits limited.

"The conditions under which the Ministry of Munitions was created were those of intense war emergency—the vital need of supplying the armies in the field with adequate, abundant, and finally overwhelming supplies of ammunition, guns, and material of all kinds—necessitated and justified every expedient and the suspension of all ordinary rules.

"The immense and thus far unmeasured resources of the United Kingdom afforded an ample field for the enterprise and energy of departmental direction, and for the organising capacity and bold initiative of British business men. Supplies were freely drawn from all parts of the Empire, and purchases from neutral states were used to supplement any deficiencies. As new needs arose, they were met. Department was added to department. Military requirements were not only satisfied, but anticipated, and vast programmes were successfully carried through. The British Army became the

* Extract from "Vital Statistics as affected by the War." —Sir Bernard Mallet.

* Extract from "Vital Statistics as affected by the War." —Sir Bernard Mallet.

best equipped and most formidable army in Europe."

The department at the beginning of 1917 undertook the Aircraft Supply Department, and in addition to guns and ammunition and all forms of army equipment, it became responsible for "tanks," agricultural implements, shipbuilding, and many other supplies. On June 28th, 1917, the Minister of Munitions, then Dr. Addison, gave an interesting review of the work of the department, in the course of which he stated that in March, 1917, the capacity for the production of high explosives was more than four times that of March, 1916, and twenty-eight times as great as that of March, 1915.

In an official memorandum issued in August, 1917, it was stated that the total staff at headquarters of the Ministry of Munitions was 13,500, and that this single Department of State was then employing two million persons, of whom about 670,000 were females; and that it was in contact at innumerable points with almost every business in the country, and was responsible for expenditure which might well amount to between £600 to £700 millions a year.

The war naturally caused a tremendous disturbance in the industrial life of the country. The Census of 1911 showed that, at that date, there were 35,750,000 persons occupied and unoccupied, aged 10 years and upwards. Of this total, 2,886,000 males and 12,704,000 females were described as retired or unoccupied, leaving 14,307,000 males and 5,851,000 females occupied. By the end of the first three years of the war, the number of men who had joined the Army and Navy was about 5,500,000, and as the great bulk of these were withdrawn from production, the total number of men and boys left in industrial occupations, including munitions, was a little over 9 millions. On the other hand, the number of women occupied in industry, including munitions, increased from 3,345,000 in July, 1914, to 4,766,000 in November, 1917, an advance of 1,421,000, or 42·5 per cent. It is instructive to note that during the same period the number of women employed in domestic service and small workshops decreased by 400,000, so that the net increase was 1,021,000. It is believed that about 670,000 women were employed on munition work, and 632,000 were engaged on other Government work, such as the manufacture of clothing and food for the troops (*Labour Gazette*, November, 1917).

Notwithstanding this vast withdrawal of man-power for naval and military service, the production of the country appears to have been not only fully maintained but actually increased. In the autumn of 1917 the Minister of Agriculture stated that the United Kingdom was the only belligerent which had increased its production of food during the war.

Lord Aberconway stated on September 27th, 1917, that "if you take the nation as a whole, our man power in production has increased 30 per cent. over normal times, and with 30 per cent. loss of a male population to do it with. Now, these are very remarkable figures, and I need hardly point out that but for the valuable help women have given us, these figures would have been impossible."

Dr. Addison stated on June 28th, 1917, that before the war the output of steel in this country had been more or less stationary at a little over 7 million tons per annum. The output then (June, 1917) was about 10 million tons, and he should be disappointed if they had not reached a 12-million ton output by the end of 1918.

With regard to coal, the production appears to have been well maintained. In September, 1917, the Chief Inspector of Mines reported that 998,063 persons were employed in 2,847 coal mines in the United Kingdom, as compared with 953,642 persons the previous year. The total output of coal in 1916 was 256,375,000 tons, as compared with 253,206,000 tons in 1915. Up to the end of March, 1916, 282,500 miners (or 25 per cent. of the labour employed at collieries at the outbreak of war) had joined the colours, and this number had increased to over 288,000 at the end of June. The replacements up to March, 1916, amounted to 116,900, leaving a net reduction of 165,300, or 14·8 per cent.

For the first nine months of 1917 the output was 187,750,000 tons, or 5 million tons less than in the corresponding period of 1916, and the production for the whole year will probably be between 247 and 250 million tons. The following table shows the production of coal in the United Kingdom, the exports (including bunker coal) and the home consumption for each of the years 1913, 1914, 1915, 1916 and 1917 (estimated):—

	1913.	1914.	1915.	1916.	1917.
Production	289,338,000	265,664,000	253,206,000	256,348,000	247,250,000
Exports and Bunkers .	98,338,000	83,027,000	59,952,000	55,000,000	48,250,000
Home Consumption .	191,000,000	182,637,000	193,254,000	201,348,000	199,000,000

It will be observed that although there has been a substantial reduction in the output of coal, the falling off in exports and bunkers has been still greater, with the result that the home consumption of coal in 1917 was about 5 per cent. greater than in 1913. As there has been a great reduction in the consumption of coal for domestic purposes, it may be safely assumed that the amount of coal used for industrial purposes has materially increased during the war, and this means in turn a corresponding increase in the production of the country, including, of course, munitions. In March, 1917, the Government took over all the coal mines in the kingdom in order to have complete control of the coal production and distribution. The price of coal at the pit's mouth was regulated so as not to exceed by more than a certain sum per ton (viz. 9*s.* in South Wales and Dean Forest and 6*s.* 6*d.* elsewhere) the price in 1913–14. This was absolutely necessary in order to secure the smooth working of the industry and to meet the charge of profiteering. Railway transport at the time was also giving the Government grave concern. In the case of coal alone 250 million tons were carried over the railways annually, and it was estimated by the Coal Controller that by having control of all the output of the mines, and being able to determine its destination—in other words, by bringing the consumption of coal as nearly as possible to the source—it was possible to save, roundly, 700 million ton-miles per annum.

There is an intimate relation between the national production and the consumption of Board of Trade units of electricity, and I have had the figures taken out showing the Board of Trade units sold by the municipal authorities for the year to March 31st, 1917, as compared with the number sold during the year to March 31st, 1914. The results are as follows:—

Board of Trade units sold for year to March 31st, 1917	1,298,000,000
Board of Trade units sold for year to March 31st, 1914	770,000,000
Increase	528,000,000 or 68·6 per cent.

It has been ascertained during the recent discussions as to the practicability of "linking up" generating stations, etc., that the average output of electricity before the war was progressively increasing at the rate of approximately 20 per cent. per annum—that is to say, if 1912 represented 100 per cent, 1913 would be 120 per cent., and 1914, 20 per cent. on 120 per cent., and so on. The returns as to electricity, the production of coal, the production of steel, the agricultural production, all point to the same conclusion, namely, that during the war there has been an increase in the production of the United Kingdom; and I am convinced that since August, 1914, our power of production has increased by at least 30 per cent.

The problem of financing the war was naturally the most formidable of the economic tasks which had to be undertaken by the Government. Our war expenditure began at an average of £1 million per day. As the Army grew and the scope of our activities steadily widened, and the prices of commodities and foodstuffs advanced, the war expenditure rapidly increased. From August, 1914, to March 31st, 1915, it averaged £2,050,864 per day; for the year to March 31st, 1916, it averaged £4,271,666; for the year to March 31st, 1917, it averaged £6,022,222; for the half-year to September 30th, 1917, it averaged £7,500,000 per day. Before the war the requirements of the Army were supplied by contracts based on a system of competitive tendering, but the inability of supply to keep pace with the demand, and the consequent rise in prices, necessitated a revision of the relationship between the Government and industry. It was agreed that the Army and Navy should have the first call on the resources of the country, and that the prices to be paid by the War Office should be regulated, not by market prices, but by the cost of production, plus a reasonable rate of profit. To determine the manufacturer's expenses a special Costings Department was established.

The result of the fixing of prices by examination of costings, in conjunction with a priority scheme by which manufacturers are required to complete Government contracts before dealing with private customers, was to secure to the Government service the full industrial resources of the country at fairly reasonable rates, but it was obvious that if the Government were to control the manufacturers' prices they must also control the cost of raw materials. Direct purchases in the world's markets and the elimination of the middle man were resorted to on a large scale. This naturally created a strong feeling of resentment, and in May, 1917, the Merchants' Committee of the London Chamber of Commerce reported that the effects of the Government action in many cases had tended to stifle and partially ruin trade. It was pointed out that it was impossible for any Government to regulate the world's commerce. High prices, it was claimed, restricted

consumption and checked waste. It was urged that high prices were the only hope of increasing production, and only thus would famine prices be finally prevented. If commerce was rendered unprofitable it would cease, and it was urged that the effect of Government control in many cases had been to divert large supplies to the free markets. By the end of the first three years of war the following commodities and foodstuffs were under Government control:—Coffee, coal, copra, diamonds, feeding stuffs, grain, jute and its fabrics, leather, maize, meat, metals, including iron and steel, oil, seed, paper, petrol, preserved meat, rubber, sugar, tanning materials, tobacco, wood and wool.

One of the largest operations undertaken by the Government was the control of the grain market. The Royal Commission on Wheat was appointed on October 11th, 1916, to maintain the supplies of wheat in this country, but later on the scope of its activities was enlarged to cover maize, barley, rice, tea, meal, grain, flour, lentils, cheese, and peas. An agreement was subsequently entered into between the British, French, and Italian Governments constituting a body, called the Wheat Executive, to buy grain for the three countries. The objects of the agreement were (1) to avoid competition in buying and (2) to prevent waste in the use of shipping. The Wheat Commission was charged with the responsibility of buying for all three countries, of dividing the charges among them in the right proportions, of shipping from each exporting country, and then of seeing by a careful system of accounts that each country paid its due share of the cost of the grain received. The Commission has conducted its business on trade lines. The cash trading capital and commission in August, 1917, was £48 millions, and the Commission had then drawn altogether £67 millions from the Treasury.

The largest purchase made by the Commission was 14 million quarters of wheat direct from the Australian Government, involving a sum of about £26 millions. Shortly after this contract was made the shipping scarcity became acute, and the great bulk of this wheat was still in Australia when the Committee* made its report in October, 1917. The Commission has largely increased the reserve of wheat which it took over from the Board of Agriculture on its appointment, and a fairly heavy loss appears to have been incurred in connection with the storage of these reserves. The decision of the Food Controller that wheat must be sold at a price allowing the public to purchase a 4 lb. loaf for 9*d.* will cost the Commission £45 million a year. The arrangement for the supply of meat to the allied armies, and when not so required, to the trade, involves very large transactions. The payments under this head for the year 1915–16 for purchase, freight, and storage amounted to £31,386,818, and the receipts for sales to £27,838,749, leaving a balance of £3,548,069, representing meat in stock plus issues not paid for. The control of the sugar supply accounted for still larger figures. For the year 1915–16 the receipts from the sale of sugar were £34,840,523, and the payments were £26,432,369, leaving a balance of receipts of £8,408,153; but in 1914–15 the payments exceeded the receipts by £7,105,747, so that there was a net excess of receipts over payments in the two years of £1,302,405.

As the war progressed and the scope of the Government's activities widened, more and more trade enterprises were taken over, and the Chancellor of the Exchequer, when explaining the increase in the expenditure on October 30th, 1917, said the largest item of the increase, viz. £74,500,000, was incurred in connection with the purchase of supplies of raw materials, such as wool, hides, and timber, and foodstuffs, such as wheat and sugar.

The first War Budget was introduced by Mr. Lloyd George on November 17th, 1914. Its main features were the doubling of the income tax and super tax, an additional ½*d.* on a half-pint of beer, and 3*d.* per pound on tea.

Mr. Lloyd George presented the second War Budget on May 4th, 1915. It contained no new taxation proposals. The expenditure for the year 1914–15 amounted to £560,474,000 and the revenue to £226,694,000 (£189,305,000 from taxes and £37,389,000 from non-tax revenue), leaving a deficiency of £333,780,000.

The third War Budget was presented by Mr. McKenna on September 21st, 1915. Under this Budget the following new taxation was adopted:—

Income Tax.—40 per cent. added to the existing rates; only half of the increase (20 per cent.) to be imposed for the year to March 31st, 1916. The exemption limit to be reduced from £160 to £130, and the abatement limit to be £120 where it was £160, and where it was £150 or £120 it would become £100. Provision was made to enable the payment of the tax by

* Select Committee on National Expenditure. Second Report.

instalments in certain cases. The alterations in the income tax were expected to produce an additional £11,274,000 in 1915–16 and £44,400,000 in a full effective year. Certain additions were also made to the super tax.

Excess Profits Tax.—This tax really constituted an additional income tax. The trades or professions liable to the tax included any carried on in the United Kingdom or owned or carried on in any other place by persons ordinarily resident in the United Kingdom. Farmers, officials, and professional men were exempt. Any business or trade to which the tax applied was liable to pay to the Exchequer a sum equal to 50 per cent. of the amount by which the profits for the "accounting period" exceeded by more than £200 the defined pre-war standard of profits. The tax only applied to periods of account terminating after August 4th, 1914, and before July, 1915. Profits earned in periods ending later were to be dealt with by subsequent legislation on the same lines. The new tax was estimated to produce £6,000,000 in 1915–16 and £37,000,000 in a full effective year.

Customs and Excise.—Duty on sugar increased from 1*s.* 10*d.* per cwt. to 9*s.* 4*d.* per cwt. Tea, tobacco, cocoa, coffee, chicory, and dried fruits, an all-round increase of 50 per cent. on the existing duties. Motor spirits, an increase of duty of 3*d.* per gallon.

Imported Luxuries.—An *ad valorem* duty of 33⅓ per cent. or its equivalent in the form of a specific tax—that is to say, on weight instead of on price—on motor cars, motor cycles, cinema films, clocks, watches, musical instruments, plate glass.

Post Office, etc.—Some important changes in postal telegraph and telephone rates were proposed, but the most important of all—namely, the proposed abolition of halfpenny postage—was abandoned as a result of pressure brought to bear upon the Government.

The fourth War Budget was introduced by Mr. McKenna on April 4th, 1916. It provided for a graduated increase of the income tax, making the maximum rate 5*s.* in the £. The duties on sugar, cocoa, coffee, and chicory were appreciably advanced, while new taxes were levied on matches and table waters. The expenditure for the year to March 31st, 1916, amounted to £1,559,158,000 and the revenue to £336,767,000 (from taxes £290,088,000, non-tax revenue £46,679,000), leaving a deficiency of £1,222,391,000.

On May 2nd, 1917, Mr. Bonar Law introduced the fifth War Budget. Under this Budget the excess profits duty was increased from 60 per cent. to 80 per cent. as from January 1st, 1917, and the entertainments tax was increased substantially.

The expenditure for the year to March 31st, 1917, was £2,198,113,000 and the revenue £573,428,000 (from taxes £514,105,000, non-tax revenue £59,323,000), leaving a deficiency of £1,624,685,000.

In order to show the change which the first three years of war have brought about in the position of the national finances, I have prepared the following table, which contains particulars of the actual receipts and expenditure for the year 1913–14 and the estimated receipts and expenditure for the year 1917–18:—

RECEIPTS.

Actual, 1913-14. £		Estimated, 1917-18. £
35,450,000	Customs	70,750,000
39,590,000	Excise	34,950,000
27,359,000	Estate, etc., Duties	29,000,000
9,966,000	Stamps	8,000,000
2,700,000	Land Tax and House Duty	2,600,000
47,249,000	Income Tax, including Super Tax	224,000,000
	Excess Profits, including Munitions Levy	200,000,000
715,000	Land Value Duties	400,000
163,029,000	Total Receipts from Taxes	569,700,000
35,214,000	Non-Tax Revenue, including Post Office, etc.	68,900,000
	Total Revenue	638,600,000
	Deficiency	1,651,781,000
198,243,000		2,290,381,000

EXPENDITURE.

Actual, 1913-14. £		Estimated, 1917-18. £
24,500,000	National Debt Services Inside the Fixed Debt Charge	17,000,000
	Outside do. . . (*c*)	194,500,000
9,734,000	Payments to Local Taxation A/c.	9,700,000
3,089,000	Other Cons. Fund Services, etc.	1,695,000
37,323,000	Total Cons. Fund Services	222,895,000
28,346,000	Army . . . (*a*)	15,000
48,833,000	Navy . . . (*a*)	17,000
	Ministry of Munitions . . . (*a*)	1,000
53,901,000	Civil Services	61,224,000
4,483,000	Customs, Excise and Inland Revenue	5,249,000
24,607,000	P.O. Services	25,980,000
160,170,000	Total Supply Services	92,486,000
750,000	Votes of Credit Balance . . (*e*)	1,975,000,000
198,243,000		2,290,381,000

(*a*) Nominal provision, the substantive provision being made under Votes of Credit.
(*c*) Including estimated interest on new Debt to be credited in 1917–18.
(*e*) The three war services account for £1,433,500,000.

The whole basis of taxation has been disturbed by the war. In 1913–14 direct taxation amounted to £93 millions and represented 57 per cent. of the total tax revenue. For the year 1917–18 direct taxation, including excess profits duty, will amount to £466 millions, or 82 per cent. of the total taxation. It will be seen, therefore, that the burden of war taxation has fallen almost entirely upon the direct taxpayers. The proportion of the total expenditure raised by (1) borrowing and (2) revenue—that is, taxation and Post Office, etc., during each of the years 1915, 1916 and 1917—was as under:

For the year to March 31st, 1915 (which included the first eight months of the war), the revenue was £576·7 millions, of which amount £405 millions were borrowed and £171·7 millions, or 29·7 per cent., raised by revenue.

For the year to March 31st, 1916, the total sum received was £1,501·3 millions, of which £1,164·5 millions were borrowed, and £336·7 millions, or 22·4 per cent., was raised by revenue.

For the year to March 31st, 1917, the amount received was £2,199 millions, of which £1,625·5 millions were borrowed and £573·4 millions, or 26·8 per cent., raised by revenue.

On October 30th, 1917, Mr. Bonar Law said the total amount of our National Debt was between £4,900 and £5,000 millions. He would take it at £5,000 millions. They were entitled, he said, to deduct from this sum the amount of the advances to our Allies and the Dominions. These items came in the case of the Allies to £1,100 millions, and in the case of the Dominions to £160 millions. They were entitled to deduct another item, that was the gift of the Indian Government to the Empire in connection with the war, which was £100 millions. Those items together amounted to £1,360 millions. That brought down the total amount of the debt to £3,674 millions. The National Debt at the beginning of the war was £645 millions, so that the increase of debt due to the war was about £3,000 millions.

The total gross debt of £5,400 millions appears to have been raised in the following form:—

Debt on December 8th, 1917.*

Funded Debt, principally Consols	£317,787,000
Terminable Annuities	24,045,000
Unfunded Debt—	
3½ per cent. War Stock	62,746,703
4½ ,, ,, ,, ,,	19,989,842
5 ,, ,, War Loan	2,066,988,385
4 ,, ,, ,, ,,	52,418,250
3 ,, ,, Exchequer Bonds, 1920	21,650,700
War Savings Certificates	101,587,016
War Expenditure Certificates	23,561,000
5 per cent. Exchequer Bonds, 1919–20–21	156,913,415
6 ,, ,, Exchequer Bonds, 1920	141,744,780
Other Debt, including Anglo-French Loan in U.S.	849,773,040
Ways and Means Advances	253,155,500
Treasury Bills (including £12,995,000 pre-War	1,059,525,000
5 per cent. Exchequer Bonds, 1922	82,209,400
National War Bonds (Post Office and Bank of England)	154,200,000
	£5,388,295,031

* Daily Telegraph, December 17th, 1917.

It will be observed that out of a total gross debt of £5,388 millions outstanding on December 8th, 1917, only £2,543 millions, or 47 per cent., had then been funded into War Stock, etc., the principal items of the unfunded debt being:—

Treasury Bills	£1,059,000,000
Other Debt	849,000,000
Ways and Means Advances	253,000,000
Exchequer Bonds	402,000,000
	£2,563,000,000

It is a matter of some urgency that a large proportion of these last items should be converted into War Loan, and this operation would doubtless be greatly facilitated if arrangements could be made whereby credit might be obtained without having to sell War Stock.

The Budget estimate provided for an expenditure of £6,275,000 per day, including £864,000 carried on the estimates and £5,411,000 on the votes of credit. In moving the vote of credit on October 30th, 1917, the Chancellor of the Exchequer stated that the expenditure for the half-year exceeded the Budget estimate by £1,237,000 per day, or an aggregate for the half-year of £222,500,000. If this rate is maintained throughout the year the total expenditure will be £2,735 millions, or £455 millions more than the Budget estimate. The Chancellor of the Exchequer explained the increases under the following heads:—Increase of monies in agents' hands abroad, £15,500,000; Advances to Dominions, £24,000,000; Purchases of foodstuffs, raw materials and ships, £74,500,000; Loans to Allies, including moneys spent by Ministry of Munitions, £65,000,000; and War Office increase, £39,000,000.

The cost of fixing the price of the loaf at 9*d.* will add £45 millions to our expenditure. The increase of pay to soldiers and sailors will add £65 millions this year, and the payments to farmers under the Potato Order will account for a further £5 millions. There seems to be no

prospect of the expenditure diminishing. The additional allowances in connection with old age pensions will call for £5,320,000 this year and about £6,000,000 per annum thereafter. Aviation will call for increased expenditure. The number of men serving abroad is continually increasing. A large number of Indian troops are now serving in Mesopotamia. As our armies advance, the cost of communications —railways and bridges—are bound to increase.

But on the other hand it is already evident that there will be a very large increase in the revenue from taxation. Excess Profits Duty was estimated to produce £60 millions more than in 1916–17, but by December 31st, 1917, it had already produced £69 millions more than in the corresponding period of the previous year. Income tax was estimated to yield £19 millions more for the whole year, but by December 31st, 1917, the yield was £15·5 millions more; while miscellaneous sources yielded a revenue of £46·6 millions against £11·7 millions in the corresponding period last year. Customs and Excise were estimated to yield £21 millions less. By the end of December the yield was only £11·1 millions less. I estimate that the total revenue for the year will amount to at least £726,000,000, or £153,000,000 more than for the preceding year.

Several attempts were made to control expenditure and check waste. In 1915, a Retrenchment Committee was appointed which made a few feeble recommendations for economies, but the scope of the inquiry was so limited that from its inception it was doomed to ineffectiveness. The House of Commons became alarmed at the growth of expenditure when on June 11th, 1917, the Chancellor made the announcement that for the first nine weeks of the current financial year our expenditure had averaged £7,884,000 per day, and a Select Committee was appointed on July 25th, 1917, "to examine the current expenditure defrayed out of monies provided by Parliament, and to report what, if any, economies consistent with the execution of the policy decided by the Government may be effected therein," and Mr. Herbert Samuel was appointed chairman. Two reports were issued at the end of 1917, and their general conclusions may be summarised in the statement that the financial control of expenditure is insufficient, and that the maintenance of the staying power of the country during a long war requires that "considerations of cost should be put on a different plane from that which they have hitherto occupied." But the House found itself quite helpless to stem the growth of expenditure. It looks very much as if nothing can be done effectively to stop the growth of expenditure until the workers become sufficiently educated in political economy to realise that this constant putting up of wages is a real disadvantage to the working classes as a whole and that it really comes out of their own pockets. Since the Committee was appointed in August, 1917, ten increases of expenditure were incurred, namely, £45,000,000 in order that the loaf might be sold at 9*d.*; £5,000,000 bonus to potato growers; £65,000,000 increase of pay to soldiers; £7,350,000 increased pay to Army officers; £20,000,000 bonuses to miners; £40,000,000 to munition-workers; £10,000,000 to railway workers; £3,000,000 to civil servants; £170,000 to Irish teachers and £400,000 to Irish police; the total making an annual increase of £195,920,000.

From 1870 down to 1914, agriculture was a declining industry. The decrease in tillage amounted to 3,883,000 acres, or 27 per cent., in England and Wales; 196,000 acres, or 6 per cent., in Scotland; and 663,000 acres, or 12 per cent., in Ireland. The number of persons engaged in agriculture at the census of 1871 was 2,487,900, and at the census of 1911 only 1,926,687. The estimated value of the agricultural production declined from £259,800,000 in 1873 to £208,000,000 in 1908, but it is probable that owing to the fall in the price of agricultural production the actual amount of foodstuffs produced in 1908 was larger than in 1873. It may be estimated that whereas in 1872 we produced 57 per cent.* of the total food consumed, the production of food in 1913 was only 42 per cent. of the total consumption. That is to say, when war broke out we were confronted with the fact that we only grew sufficient food to feed the population three days out of every week. Owing to the fact that during the first eighteen months of the war our mercantile marine continued to perform its functions almost as in time of peace, the gravity of this dependence upon foreign supplies of food was not fully appreciated, and the Government did not take any steps in the early stages of the war to control the farmers. The necessity of increasing the home production of food was, however, generally recognised, and at the beginning of 1917, in order to encourage farmers, a price guarantee was given for wheat, oats and potatoes.

* Professor Starling, letter in the *Times*, February 5th, 1918.

One of the first fruits of this change in the national agricultural policy was the passing of the Corn Production Act. On April 24th, 1917, Mr. Prothero, in moving the second reading of this measure, said national safety demanded a larger supply of home-grown food, and national welfare demanded that we should retain as much as possible of the rural population. From these two points sprang the two principal features of the Bill, viz., a minimum price and a minimum wage. The Act, which is in four parts, proposes to obtain an increase of the arable area by means of a minimum price for wheat and oats, as follows:—

MINIMUM PRICES FOR WHEAT AND OATS.

	Wheat price per quarter. *s.*	Oats price per quarter. *s.*	*d.*
1917	60	38	6
1918, 1919	55	32	0
1920, 1921, 1922	45	24	0

Part 2 provides for the institution of a minimum wage of 25*s.* per week for agricultural workers and for the creation of wages boards to settle disputes as to wages. Part 3 provides that no landowner shall be allowed to use for his own private advantage the guarantee of minimum prices given by the State for the public benefit. Part 4 provides that the State shall have power to secure that the land is properly cultivated.

Mr. Prothero said if we could grow at home 82 per cent. of all the food we require, we should be safe in an emergency. We could obtain that result if we could add eight million acres to the existing arable area—that is to say, if we increased it from 19 million acres to 27 million acres—and the number of additional men who would be required on the land would be about 250,000.

The Corn Production Act was, however, much less ambitious. It proposed to make such a substantial increase in the arable area as was possible within the limits of six years. In 1914 the total amount of acreage under corn crops, wheat, oats, and barley was 7,678,000. In 1915 it had risen to 8,041,000, but as 250,000 agricultural workers had enlisted up to the end of 1915, the labour difficulty by that time had become acute, and the acreage in 1916 decreased by about 300,000 acres. In 1917 there was an addition of 330,000 acres in England and Wales and 750,000 acres in Ireland. The various measures taken did result in a moderate expansion in the home production of food, and the following table shows the increase in the area under corn crops, potatoes, etc., between 1914 and 1917*:—

	1914. 1,000 acres.	1917. 1,000 acres.	Increase or Decrease. 1,000 acres.
Arable land	19,414	19,652	238
Wheat	1,906	2,104	198
Barley	1,873	1,797	– 76
Oats	3,899	4,762	863
Total corn crops	7,678	8,663	985
Potatoes	1,209	1,365	

The result of this extension of acreage of the food supply is indicated in the table appended, which gives the total production of corn crops and potatoes at each of the harvests 1914–7:—

	1914. 1,000 qrs.	1915. 1,000 qrs.	1916. 1,000 qrs.	1917. 1,000 qrs.
Wheat	7,804	9,239	7,472	7,979
Barley	8,065	5,862	6,612	7,185
Oats	20,664	22,308	21,334	23,964
	36,533	37,409	35,418	39,128
	1,000 tons	1,000 tons	1,000 tons	1,000 tons
Potatoes	7,476	7,540	5,468	8,603

The average price of wheat in the second week of December, 1917, was 70*s.* 7*d.*, as compared with 42*s.* 1*d.* in the corresponding week of 1914. The position with regard to live stock is not satisfactory. The figures are as under:—

	1914.	1917.
Horses	1,851,042	1,870,770
Cattle	12,184,505	12,342,268
Sheep	27,963,977	27,770,553
Pigs	3,952,615	2,998,657

It is gratifying to see an increase in the number of horses and cattle, but the falling off in pigs is serious, and the decrease in the number of sheep is also unsatisfactory.

Farmers were treated very lightly with regard to the income tax. Formerly they were assessed to income tax at one-third of their rent. Since the war the assessment under Schedule B has been raised to the amount of the whole rent, but farmers do not pay any excess profits duty. With regard to the bonus to potato-growers, Mr. Clynes said (November 13th, 1917, House of Commons): "The charge upon the Exchequer involved by the War Cabinet's decision to compensate growers who sell potatoes of the 1917 crop below the guaranteed price of £6 per ton is estimated not to exceed £5,000,000."

* "Prospects of the World's Supplies of Food after the War."—Sir R. Henry Rew.

The value of the agricultural output in 1908 was about £208 millions. The agricultural index numbers have been as follows:—1913, 112; 1914, 111; 1915, 138; 1916, 178. The value of the production for 1917 may therefore be estimated at £400 millions. The labour and other difficulties with which the farmers have had to contend have, of course, been very great, but on the whole the result of the effort to increase the home production of food is disappointing, and it does not appear, in spite of the extraordinary inducements held out to farmers, that at the end of the war we shall have materially emancipated ourselves from dependence upon foreign food supplies.

(*To be continued.*)

DAMASCENE STEEL.

By Colonel Nicholas T. Belaiew, C.B.

One of the many articles which contributed to the world-importance of Indian trade was the famous Indian steel. It appeared in Western Europe during the Middle Ages, under the name of damascene, or Damascus steel. By another trade route through Persia and the Caucasus it found its way to Russia, under the Arabian name of "foulad," which the Persians spelt as "poulad," and the Russians as "bulat."

We find, for instance, in the journal of Prince Zvenigorodsky, the Russian Ambassador in Persia, the following words of the Shah Abbas: "Helmets and shishaks are manufactured in our country, but a good 'bulat' is brought here from the Indian kingdom."

On the other hand, from the twelfth century comes the testimony of the Arab geographer, Edrisi: "The Hindoos excel in the manufacture of iron and in the preparation of those ingredients along with which it is fused to obtain that kind of malleable iron usually styled Indian steel. They also have workshops wherein are forged the most famous sabres in the world."

The iron and steel industry was highly developed in ancient India. A witness to this exists not only in the famous wrought-iron pillar of Delhi, but in many other specimens, some of them at least being undoubtedly high carbon crucible steels.

To this last category belonged the wootz, or small cakes of carbon steel, from which the damascene blades were manufactured. Some of such cakes were investigated by Réaumur, but he found nobody in Paris who could forge them. Some others were presented to the Royal Society by Dr. Scott, of Bombay, and brought to this country by Dr. Pearson. Faraday took a keen interest in them, and his investigation of alloy steel, conducted in conjunction with Stodart, was the result.

Subsequent researches of General Anossoff, Professor Tchernoff, and the author, led to show that damascene steel was a very pure high carbon crucible steel, with excellent mechanical qualities and a splendid watering.

In his recent paper on this subject to the Iron and Steel Institute, the author explained that the splendid watering of the Oriental blades showed the amount of mechanical treatment the original cake was subjected to; this watering, from the point of view of modern metallography, was its macrostructure. In order not to spoil this watering the Oriental maker never dared to exceed the temperature of about 700 degrees.

One of the many results of this enforced carefulness was the spherodising of cementite into globulites, and the subsequent ductility of the alloy, which struck both the ancient and modern explorer.

The author wishes to draw the attention of all interested in the production of high carbon and alloy steels to the many possibilities, especially from the point of view of after-war trade, which the damascene steel, or, we may better say, the "damascene process," offers to the steel-maker in this country and in the Indian Empire.

SIGNALLING IN MINES.

A great deal depends on satisfactory signalling down a mine, as coal, when "won" from the coal-seam or face, is not "effectively got" until it has been tubbed and raised to the surface of the pit.

Ineffective signalling means delays and loss of output, which at the present moment is a vital matter. Especially is this so, on account of the very large comb-out which is taking place in all mines throughout the country. There is also the factor of "safety" in signalling. The disaster at Senghenydd Colliery was supposed to be caused through open sparking between signal wires. Many people have made experiments to try to overcome such sparking or break-flash, but such efforts have been mainly in the direction of curing sparking on the old-principle apparatus and existing designs of signalling system gear, and this has added to the already cumbersome, and to some extent complicated, apparatus.

It has been left to Mr. W. de M. Landon, A.M.I.E.E., Member of the Association of Mining and Electrical Engineers, to evolve a system where only one wire is employed, with the earth for return, and where only six volts pressure actuates the system. There is no possibility of sparking on the system (break-flash is cut out between wires, as only one wire is employed), and a two years' trial in a network of Lancashire mines has proved the system absolutely satisfactory. A system of relays operates the signalling bells, and a piece of apparatus called an "interrupter" (which swings on the line wire) actuates the relays. The system is one that colliers can easily understand. Only very small sets of batteries are needed, and the system uses far less battery power than any other known system.

STUDY OF AMERICAN PAPER PULPS.

A report of recent scientific study of paper pulps, particularly those of American manufacture, has been published by the United States Bureau of Standards as Technologic Paper No. 88. Samples of pulps, each representing a different method of preparation, have been examined to determine their chemical properties. The loss in weight produced by reagents, causing hydrolysis and oxidation, and the gain in weight when nitrated have been determined with the same pulps. The effect of sunlight, temperature, and ozonised air on the chemical constants of ground wood has been ascertained.

Much work had already been done both with the woods from which the pulps are produced and with the pulps themselves in studying the properties of the fibres, and in seeking to find means of judging the paper-making value by laboratory tests in advance. The results are scattered over a wide range of chemical literature, and for the most part are concerned with pulps produced in other countries. The present work has been carried out chiefly with typical American pulps produced by the several well-known methods in order to ascertain their chemical characteristics as far as possible with the few reliable quantitative methods available. Copies of the paper may be obtained at 5 cents (2½*d.*) each from the Superintendent of Documents, Government Printing Office, Washington, D.C.

KAPOK.

The use of kapok and its substitutes has undergone considerable expansion during the present war, particularly as a filling material for lifebelts and waistcoats and other forms of life-saving appliances. In view of the utilisation of kapok and other flosses for this purpose, an investigation has been carried out by Messrs. C. F. Cross and E. J. Bevan, with the object of devising a rapid method for determining the approximate value of representative samples, and the results have been published in *Journ. Soc. Dyers* (1916, 32. 274).

It has usually been assumed that the impermeability of the material to water is due to the presence of such constituents as oil, wax and resin in the wall of the fibre; but it has now been found that this is not the case. The amounts of such constituents very considerably in different samples, but the variations do not show any correlation with the resistance of the fibre to the admission of water, and the resistance is not appreciably affected by the removal of these substances.

Three tests are recommended for the rapid determination of quality in the laboratory. The first of these is observation of the degree of lignification of the fibre by the phloroglucinol test; the best samples do not give any reaction with phloroglucinol, but the lower qualities give a reddish-brown or even a magenta-red colouration, typical of lignocelluloses. The second test consists in the microscopical measurement of the diameters of the fibres; the more uniform the diameter, the higher is the quality of the material. The third test is carried out by floating the fibre on the surface of aqueous alcohol, of sp. gr. 0·928, and determining the relative rates of wetting and sinking of the different samples.

Particulars are given of the flotation and resistance to submersion of certain appliances made with kapok. The life-saving jacket tested contained 700 grams of kapok, and, since the average floating power of the compressed fibre is equal to fifteen times its weight, the jacket, when submerged, exerts a lifting power of 10·5 kilograms. When placed in water and partially submerged by a weight of 9 kilos, the jacket still supported an extra load of 1·3 kilos after seventy-two hours; after one hundred hours it still required an addition of 1·0 kilo to submerge it, and after 192 hours the weight required was 0·9 kilo.

NOTES ON BOOKS.

Sir William Ramsay, K.C.B., F.R.S. By Sir William A. Tilden, F.R.S. London: Macmillan & Co., Ltd. 10*s.* net.

No one who cares for competent biography, and is interested in the development of science and the methods of scientific research, can afford to neglect Sir William Tilden's admirable memorials of a life of high scientific aspiration and notable scientific achievement.

From childhood to death William Ramsay's life was uniformly happy and successful. By his own wish he was engaged from early youth in congenial scientific pursuits; he had neither poverty nor ill-health to contend with; no family troubles nor enemies, public or private, to distract his mind; and his biographer cannot so much as hint at any storm and stress periods such as often punctuate some of the most humanly interesting lives. For Ramsay, however, ample excitement was provided by his experiments and discoveries, and he was never daunted by difficulties of apparatus or material, although much of his most fruitful research was of necessity carried on in minute spaces and with minute quantities of gas, and involved not only the most skilled manipulation, but minute and laborious sifting of numerical results.

It is not given to many chemists to discover a new element; and we imagine Ramsay's most thrilling moment must have come to him when he was forty-two years old, with his triumphant isolation of a new constituent of our atmosphere. "The last twenty years of the nineteenth century,"

writes Sir William Tilden, "witnessed two discoveries in physical science, namely, the observation of X-rays and the isolation of the argon series of gases, which equal, if they do not surpass, in significance and interest the discoveries of any previous period. Of the two, the latter must be regarded as the most surprising, because it was not only unexpected, but the existing evidence appeared conclusive against the possibility of such a discovery." Of the important part played therein by Lord Rayleigh, and the preliminary investigations regarding the atmospheric gases which led eventually in 1894—an unlucky but obvious misprint gives the year as 1914—to the isolation of argon by Ramsay, and his later discoveries of helium, neon, krypton, and xenon, his biographer gives a careful, historical, and scientific account, adequately documented; while an interesting appendix describes, with diagrams, the apparatus used by Rayleigh and Ramsay for isolating argon in bulk from the air. Ramsay's work on radium, into which he threw himself with characteristic zest after the isolation of radium salts by Madame Curie in 1902; the researches which occupied his later years; his activities in connection with the Chemical Society, the Society of Chemical Industry, and the British Association, are of course all sufficiently dealt with. A chapter is devoted to his well-known and pronounced views on education and competitive examinations, which are presented without bias by one who is, however, obviously of a less dogmatic and more conciliatory spirit in these matters; while other aspects of a life and character completely unspoilt by success and fame—Ramsay's friendships, his popularity with his students, his travels, his gaiety of spirit, and his practical benevolence—are all indicated with sympathetic and appreciative understanding.

Ramsay was at the least a singularly happy example of one of his firmest educational convictions, that the good teacher must also be at the same time a learner—which means in physical science an investigator. From 1874, when he was appointed assistant to Professor Ferguson of Glasgow University, till 1912, when (four years before his death) he retired from the chair of Chemistry at University College, London, which he had occupied for a quarter of a century, he successfully combined the arduous duties of the teaching profession with his own independent researches. All his students can testify to the result.

Joseph Pennell's Pictures of War Work in America. Philadephia and London: J. B. Lippincott Company. 9*s*. net.

Some eighteen months ago the *Journal* contained a review of Mr. Pennell's "Pictures of War Work in England." Since then the artist, who believes that "the place for an American at the present time is home," has transferred his headquarters from London to New York, and he has busied himself in carrying on in America the remarkable series of drawings which he started in this country.

For the ordinary reader on this side of the Atlantic the interest of the book is twofold: the drawings are an artistic feast, and they give a comforting sense of the energy which our Allies are throwing into the gigantic task of providing munitions of war. The subjects are taken principally from ship-building yards, gun-pits and shell factories; and they afford Mr. Pennell opportunities for those tremendous effects of light and shade in which he specially delights.

The thirty-six lithographs which the book contains are all admirable, though they attract in different ways: some, such as the armour-plate press, the gun-pit, and the "biggest hammer in the world," by their bold contrasts of black and white; some, such as the transports and the building of destroyers, by their delicate drawing. The riveters' workshop is curiously suggestive of a cathedral. One of the most striking sketches is that of the locomotive shop, in which a huge engine is seen suspended high in the air—the sheds in which the locomotives are constructed being too small to allow them to be moved about in any other way. Another remarkable drawing shows an American munition town, the houses of which can be put together in forty-five minutes!

Mr. Pennell comments on the fact that in America women have not to any extent gone into the factories, mills and shipyards of the country, and he hopes they never will. If the United States can turn out all the necessary munitions without calling upon their woman power, so much the better; and it will no doubt be pleasant for the Central Powers to know that we still have this immense resource practically untapped.

Forestry Work. By W. H. Whellens. London: T. Fisher Unwin, Ltd. 8*s*. 6*d*.

During the last thirty years we have had Forestry Commissions and Committees, ending recently with the Forestry Report of the Reconstruction Forestry Sub-Committee. Concurrently with these we have had only a comparatively small number of books published on the subject. Now we have the latest on this subject, dealing chiefly with all the various processes to be undertaken in connection with afforestation by a most practical forester. As there is a definite sequence in all the operations from the time of clearing the ground to the day of cutting the trees when they are financially ripe, so in this book a similar order is followed. In addition to "The First Steps towards Afforestation," "Raising the Plants," "Preparing the Ground for Transplants and Transplanting," we have separate chapters on "Preparing the Planting Area," as also "Stocking the Ground." "Impervious Pans," which are somewhat common in parts of England, have to be broken up before planting operations can profitably be undertaken. The "Raising of the Plants" may be done in the "Home Nurseries," or in "The Temporary Forest

Nursery." Later on we come to "The Tending of the Plantations," as well as "Clearing of the Crop." Again, there are "Insect and Fungoid Enemies," coming unasked for, but which have to be combated. "Measuring the Ground" is another process requiring care. In the 236 pages of this book all these subjects are dealt with fully, and all the processes accurately described. During the last few years we have had quite a number of books dealing with forestry, but none so fully going into all the proprietary work of afforestation. Although this work is chiefly meant for woodmen and foresters, it should be of the greatest use to consulting foresters, forest officers, estate agents, and all lovers of the forest. The results of other most complicated experiments are mentioned here, such as the most profitable "rotation" under which it is best to grow trees. In other words, after how many years can trees which have been planted in a wood be cut down? For instance, 120 to 150 years elapse in the case of oak, 90 to 100 years in the case of ash or sycamore, while a period of 70 to 80 years is usually sufficient for Scots pine, larch, or Douglas fir. "Nursery Notes" and "Beating Up" of plantations are each treated separately. Towards the end of the book there are 40 tables of measurements of length or area, such as inch, link, foot, yard, pole, chain, furlong, and mile, besides square chain, rood, or acre. The notes on fencing, draining, number of plants per acre, are most complete. The timber weights, as well as the notes on the technical properties of wood, are most useful. The writer of the work found difficulty in obtaining such data, so that what he mentions are the results of careful observations extending over a number of years, and all are based on his practical experience.

A. H. UNWIN.

GENERAL NOTES.

THE BRITISH SCIENTIFIC PRODUCTS EXHIBITION.—The British Science Guild, with the assent of the Ministry of Munitions and the approval of the Board of Trade, is arranging for an exhibition, to be held at King's College, Strand, London, from August 12th to September 7th, of products and appliances of scientific and industrial interest which, prior to the war, were obtained chiefly from enemy countries, but are now produced in the United Kingdom. The chief purpose of the exhibition is to make clear the necessity of scientific research with respect to the application of its results in the arts and industries; and, further, to display to the public and to those intimately concerned how much has been successfully achieved in this regard since the advent of the war in the production of articles of prime importance, not only for the home but also for foreign markets, hitherto manufactured in or imported from other countries.

THE CHANNEL FERRY.—This project, laid aside some years ago, is to be revived, according to the paper recently published by the British Chambers of Commerce in Paris, by Sir John Pilter and M. de Cordemoy. We take the project to mean, not a supersession of the tunnel scheme, which alone, for many of its advocates, seems necessary, but an adjunct as well, and in the meanwhile, during the construction of the tunnel, a temporary provision. The paper implied a scheme of steam ferries of 25,000 tons gross accommodation, twice a day, 300 ten-ton waggons, two decks above waterline. In the session of 1905, a proposal was made and subsequently withdrawn, the particulars of which the present writer was enabled, through the courtesy of Lord Weardale, the Chairman of the Channel Ferry Co., to give in the engineering press of the time. The ferry boats at that period were designed by the late Sir William White and Sir W. Armstrong, Whitworth and Co., who had much experience in the design of American lake ferry steamers, etc.

ECONOMY OF COAL.—In his presidential address to the Society of British Gas Industries, Sir Robert Hadfield, F.R.S., gave some information he had been able to obtain regarding a discussion on coal and fuel consumption which took place in November last at a meeting of the Verein Deutscher Ingenieure at Charlottenburg. Professor Brabbee, on the occasion referred to, pointed out that Germany, at the present rate of extraction of coal, would probably have sufficient for another thousand years, England 600 years, and France 500 years, but Germany possessed only about 15,000 square kilometres out of the, roughly, 550,000 square kilometres of coalfield of the earth, while the Union and China possessed 200,000 square kilometres each. Dr. Brabbee dwelt upon the advantage of the central heating system as compared with isolated heating, and showed that many so-called coal economisers were quite worthless. He calculated that, with strict observance of all principles at present recognised as correct, at least 25 per cent.—that is, about 8,000,000 tons of coal—would be saved annually in domestic consumption of fuel, corresponding to an average value of, say, £6,000,000. Turning to America, Dr. David Moffat Myers had pointed out that in one steel-mill which he had investigated there was a waste going on of no less than 40,000 tons per year. This, at a value of £1 per ton, meant £40,000, and yet the plant was a comparatively modern one. Sir Robert Hadfield expressed the hope that our new Fuel Research Board will examine this question with the idea of avoiding the serious waste which unfortunately exists in this country as in America. "Whilst there may be two plans of operation worthy of consideration, the autocratic and educational, surely," he said, "the latter, in which patriotism and efficiency furnish the motive force, would be the best to follow."

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE ECONOMIC CONDITION OF THE UNITED KINGDOM AFTER THREE AND A HALF YEARS OF WAR.

By Edgar Crammond,

Late Secretary of the Liverpool Stock Exchange; Managing Director of B.S.T. Limited.

Lecture II. (*concluded*).—*Delivered February 25th*, 1918.

The war has brought home to the people of the United Kingdom the fact that British sea power depends almost as much upon the mercantile marine as it does upon the Royal Navy. allied countries; 14 per cent. had been occupied in carrying foodstuffs and raw materials on behalf of the Government and the Allies, and the remaining 43 per cent. had been left to British shipowners under State regulations as to its use. The assistance we were rendering to our Allies in respect of shipping was on a scale unprecedented in any war. Out of a total of between 3,000 and 4,000 British ocean-going steamers we had dedicated over 500 to the exclusive service of France, Italy, and Russia.

It is noteworthy that, in spite of these vast calls, our mercantile marine was able to fulfil in a very complete manner its vital functions in the carriage of foodstuffs and raw materials in the first year of the war, as is shown in the following table:—

Imports.

	Peace conditions. Year to July 31st, 1914. Tons.	War conditions. Year to July 31st, 1916. Tons.
Food, drink and tobacco	16,100,653	15,579,574
Raw materials and articles mainly manufactured	26,376,656	22,500,576
Articles wholly or mainly manufactured	6,452,185	3,537,603
Articles for which weights are not given—estimated weight	6,672,000	5,674,608
Totals	55,601,494	47,292,361

A report issued by the Mercantile Marine Service Association in December, 1917, showed that 76,000 officers and men were serving in the Royal Naval Service and about 33,000 officers and men in the Royal Naval Volunteers, while more than 8,000 seamen had been drowned or killed, and that 4,000 others were prisoners. Lord Beresford stated on May 3rd, 1916, that we started the war with 11,353 vessels of over 400 tons. The Admiralty requirements were between 2,000 and 3,000 vessels. That left about 8,300 vessels to carry on the trade of the country at that time. Earl Curzon said on the same date that over 43 per cent. of British shipping had been requisitioned for the naval and military and essential civil needs of the

Throughout the first twelve months the tonnage entrances and clearances diminished by 29·8 per cent., but the weight of the cargoes carried decreased by only 12·7 per cent.

The fact that the ships remaining were able to carry the trade is accounted for in several ways. First, a number of the vessels taken up by the Government were passenger ships which were not, in times of peace, large cargo carriers; secondly, the steerage accommodation on a number of emigrant ships was taken out and the space used for carrying cargo; thirdly, the ships carrying the cargo have been more fully loaded.

"During the first eighteen months of the war, from August, 1914, to February, 1916, the nation depended in the main for its overseas

supplies on the enterprise and exertions of the individual traders and shipowners, and its supplies of all essentials were maintained, although from one-fifth to one-fourth of the ocean-going ships had to be devoted to war services. During the next twelve months, from February, 1916, to February, 1917, the employment of ships was limited to voyages approved by the Government, but the management of the ships on such voyages was left in the hands of the shipowners, and the cargoes carried on these voyages were in the main provided by the traders; and, again, the nation's supplies of all essentials were maintained, although more of the carrying ships had had to be devoted to war services and material help had to be given our Allies."* The reduction by nearly one-half of the mercantile tonnage available for the sea commerce of the world naturally exercised a profound influence upon freights, and *Fairplay* for December 21st, 1916, contained a diagram which showed that outward freights in 1916 were 614 per cent. and homeward freights 570 per cent. of those in force in 1900, but this does not mean that the aggregate earnings of British shipping in 1916 were six times as great as those received in 1900, as throughout 1916 about 55 per cent. of the tonnage was run on Blue Book rates, 20 per cent. on directed rates, and only 25 per cent. at the current market rates. From a careful examination of all the available data, I have arrived at the conclusion that the following is a fair estimate of gross earnings, working expenses, and net profits of our shipping industry for the year 1916:—

"On its formation (in December, 1916) the present Government determined to requisition all British ocean-going steamships, and it did so for the purpose of securing the whole of the profits to be made from the freights over and above the Blue Book rates paid on a time basis for the use of the ships. The terms offered were (1) that the shipowner should be paid for the hire of his ship rates which had been fixed in 1914, and which, according to the Chancellor of the Exchequer, were, by reason of the great increase in operating charges, then below the pre-war rates of earnings; (2) that all established steamship lines should maintain at home and abroad their organisations, being reimbursed the actual net cost of maintaining the same; (3) that with such organisations the established lines should run for the profit of the State their own and any other vessels entrusted to their care; and (4) that in the event of a vessel being lost through a war peril, the shipowners should receive by way of compensation a sum which represents on the average about two-thirds of the cost of replacement." *

I estimate that the gross freights earned by the British mercantile marine, all of which was practically worked on Government account, in 1917 amounted to about £480 millions.

Early in 1917 the Government adopted a policy of building standard cargo ships in private yards, the vessels being the property of the State and being run by the shipowners' organizations on behalf of the State. At the same time the War Cabinet decided to establish, as a means of increasing the shipbuilding resources

BRITISH SHIPPING—ESTIMATED GROSS EARNINGS.†

		Year 1916.
Gross earnings—		
11,000,000 tons at Blue Book rates, say, an average of £9 per ton. . . .	£99,000,000	
4,000,000 tons partly under directed rates, *i.e.* carriage of sugar, meat, wheat, iron ore, etc., say, an average of £22 per ton	88,000,000	
5,000,000 tons free, *i.e.* at current market rates, say, an average of £36 per ton	180,000,000	
	————	£367,000,000
Working expenses—

Average dividend, say, 10 per cent.		

* Annual Report of the Liverpool Steam Ship Owners' Association for the year 1917.

† "The British Shipping Industry," by Edgar Crammond.

of the country, four national shipyards, with accommodation for thirty-two ships.

The second great phase of the war, so far as the mercantile marine was concerned, dated from February, 1917, when Germany began her intensive submarine campaign. The official returns show that from February, 1917, to the end of January, 1918, 827 ships of 1,600 tons gross and over and 302 ships of less than 1,600 tons gross had been sunk. The *Times* of January 5th, 1918, contained the following message from its New York correspondent, dated New York, January 4th :—

"Mr. Grasty, in a message from London to the *New York Times*, gives the following shipping figures, which, he says, have been obtained from a reliable source :—

	Total tonnage.
British ships over 1,000 tons, August, 1914	16,841,519
Loss by enemy action and otherwise, less new construction, purchase and captures . . .	2,750,000
Ships remaining, January 1st, 1918	14,091,519

These important figures, the message says, tell accurately the story of the results of the submarine campaign against British shipping.

"In a statement issued to the press and published in the *Times* on August 4th last, it was pointed out that the ocean-going tonnage on the Register of the United Kingdom, inclusive of prizes, was a little over 15,000,000 tons, of which 14,000,000 tons were employed in home service. Of the 14,000,000 tons thus employed, only about one-half was available for the trade of the country. About 6,500,000 tons were allocated entirely to the needs of the Navy, the Army, our Allies, and the Dominions overseas. A further million tons, or thereabouts, were being used for these purposes for the outward voyage, and were therefore lost to our export trade, but were available for imports."

Sir Eric Geddes, speaking in the House of Commons on December 30th, 1917, said : "The actual tonnage of war vessels and merchant vessels combined which we have finished in 1917 will equal the output for the record year 1913, in which year the equivalent of 2,280,000 tons gross of warships and merchant vessels was launched, viz., 1,920,000 tons of merchant shipping and 362,000 tons gross of war vessels.

The total gross tonnage of the British mercantile marine appears to have declined from nearly 21 million tons in July, 1914, to between 17 and 18 million tons gross at the end of 1917.* On November 1st, 1917, Sir Eric Geddes informed the House: "Our present position in merchant shipping is an interesting phenomenon of the war. The fact shows how quickly our surplus resources can be wasted, and we can take courage in remembering that at the same time we have grown strong where we were weak. Some never thought it was possible in the early months of the war to help the great host of our Allies in France and the other theatres of war, but they are now equipped on a scale never dreamt of before. This effort was achieved in part at the cost of our mercantile marine, and also in part at the cost of our Navy. If we had continued during the war with our merchant shipbuilding on its pre-war level, we should have been between two and three million tons to the good, but expenditure of effort in one direction calls for reconstruction in another, and we were fortunate that we started well supplied. The House will recollect that even so, we are less than 2½ million tons down on the register of big ships. Might the country not justly take courage from the fact that in 1917, with our munitions effort at the maximum and with a call upon our man-power which reduced our available resources to the minimum, we shall have produced naval and mercantile tonnage to an extent almost equal to the best year ever recorded in our history, and in 1918 it will certainly be very much greater?"

The gross tonnage of merchant shipping launched in the United Kingdom during each of the past five years was as follows :—

	Tons.
1913	2,127,000
1914	1,728,000
1915	650,919
1916	541,552
1917	1,163,474

The position of British shipping and the maintenance of our foreign trade during the war naturally exercised a profound influence upon the economic life of the people. At the outbreak of hostilities, the insurance market was paralysed for a short time. Before the crisis became acute, the war risk was nominal,

* The Official Return issued March, 1918, showed that the losses through enemy action and marine risks from the outbreak of war to the end of 1917 were :—

		Gross tons.
		7,079,492
Output of merchant shipbuilding in United Kingdom . . tons gross	3,031,555	
Enemy tonnage captured ,, ,,	780,000	
		3,811,555
Net loss		3,267,937

but when the position began to look black it rose to 4 per cent.; immediately after the outbreak of war it was 10 guineas, and two days after the declaration it was 20 guineas per cent. Commerce could not adapt itself within a short period to such violent change, and for a few days shipping was disorganised and the foreign exchanges completely broke down. This naturally caused a great disturbance in our foreign trade. Immediately after the outbreak of war the imports fell heavily. The figures for August, 1914, were 24·3 per cent. less than in August, 1913. The decline continued until October, 1914, when it amounted to 28·1 per cent. In November there was a marked recovery, and from that month there was a steady and continuous rise in the value of the imports. This continued throughout the whole of 1915, 1916, and 1917. The effect of the war on export trade was much more serious. The falling off in August, 1914, amounted to 45·1 per cent., and this had only been reduced to a decrease of 39·3 per cent. in December; but from that date onwards there was a steady improvement, and by the end of May, 1915, values had reached the figure shown for 1913. The course of our foreign trade, month by month, over the whole of the war period and the growth of the excess of imports over exports are shown in the graph on page 597.

Over the whole of the war period—that is, from August, 1914, to December 31st, 1917—there was an excess of imports over exports amounting to £1,301 millions, or at the average rate of £372 millions per annum. For the year to December 31st, 1917, the excess of imports over exports was £461·4 millions. The average excess of imports over exports for the three years 1911 to 1913 was £134·3 millions. The excess of imports over exports during the war period was, however, considerably greater than appears from the Board of Trade figures, which down to June, 1917, did not include Government purchases abroad. No exact data have been published for calculating the volume of these purchases, but in the latter part of 1916 it was announced that the direct purchases by our Government in the United States amounted to about £12 millions a week. From July, 1917, onwards, the figures included, for the first time, all Government imports and exports so far as figures were available, except exports for the use of H.M. forces on active service. The figures relating to our foreign trade are certainly impressive. That notwithstanding the withdrawal of so many workers and the dislocation of our shipping and finance we should have been able to maintain our exports at such a high level is a magnificent tribute to the industry and resource of the British people.

In considering the excess of imports over exports, it must be remembered that the Board of Trade returns do not disclose what are termed "invisible imports and exports." The exports are given "F.O.B.," that is to say, free on board; and the value of the imports are returned "C.I.F.," that is to say, cost, insurance, and freight. In other words, the official returns debit us with insurance and freight on imports and do not credit us with insurance and freight on exports. The freight and insurance now represent a much larger proportion of the total cost than they did in time of peace, when they were about 8 per cent. In addition to carrying two-thirds of our own sea-board trade and half the sea-board trade of the world, we also finance and insure considerably more than half the world's trade. The magnitude of our earnings from underwriting may be gathered from the fact that the premiums paid at Lloyd's in 1913 amounted to £12 millions, and in 1916 they reached £34 millions, while in 1917 they were considerably more (*Daily Telegraph*, December 11th, 1917).

In pre-war times, the marine companies' income would have been in the proportion of 6 to 4 as compared with Lloyd's, but it may be assumed that in 1916 the marine companies' income would not amount to more than Lloyd's. This would give total premiums of £30 millions in 1913 and about £68 millions in 1916, and for 1917 the total probably reached £90 to £100 millions.

In order to show the true state of our foreign trade balance, I have prepared the following estimates of the manner in which our trade balance was adjusted during each of the four years 1914–17:—

FOREIGN TRADE, 1914.

	£
Debit Items—	
Imports of Commodities . . .	697,400,000
Bullion and Specie—Gold . . .	58,642,000
Silver . .	11,953,000
Loans to Allies and Dominions .	40,000,000
Imports on Government A/c. . .	100,000,000
	£907,995,000
Credit Items—	£
Exports of Manufactures . . .	430,200,000
Re-exports	95,500,000
Exports, Bullion and Specie—Gold	30,599,000
Silver	10,889,000
Interest on Investments abroad .	200,000,000
Earnings of Shipping, Banking Insurance, etc.	140,000,000
	£907,188,000

FOREIGN TRADE, 1915.

	£
Debit Items—	
Imports of Commodities	851,900,000
Bullion and Specie—Gold	10,828,000
Silver	10,560,000
Loans to Allies and Dominions, and Investments in French, Russian and Italian Bonds.	240,000,000
Imports on Government A/c.	200,000,000
	£1,313,288,000

	£
Credit Items—	
Exports of Manufactures	384,900,000
Re-exports	99,100,000
Exports, Bullion and Specie—	
Gold	39,218,000
Silver	7,360,000
Interest on Investments	180,000,000
Earnings of Shipping, etc.	200,000,000
Banking Insurance	60,000,000
Sale of Foreign Investments	250,000,000
Moneys borrowed abroad	100,000,000
	£1,320,578,000

FOREIGN TRADE, 1916.

	£
Debit Items—	
Imports of Commodities	949,200,000
Bullion and Specie—Gold	17,790,000
Silver	13,677,000
Loans to Allies and Dominions	540,000,000
Imports on Government A/c.	250,000,000
	£1,770,667,000

	£
Credit Items—	
Exports of Manufactures	506,500,000
Re-exports	97,600,000
Exports, Bullion and Specie—	
Gold	38,449,000
Silver	10,741,000
Interest on Investments	170,000,000
Earnings of Shipping, etc.	300,000,000
Banking Insurance, etc., say	50,000,000
Sale of Investments and Moneys borrowed abroad	600,000,000
	£1,773,290,000

FOREIGN TRADE, 1917.

	£
Debit Items—	
Imports of Commodities	1,065,256,000
Loans to Allies and Dominions	600,000,000
Imports on Government A/c.	600,000,000
	£2,265,256,000

	£
Credit Items—	
Exports of U.K. Produce and Manufactures	525,309,000
Re-exports	69,552,000
Interest on Investments	150,000,000
Earnings of Shipping, etc.	480,000,000
Banking Insurance	160,000,000
Sale of Investments and Moneys borrowed abroad	900,000,000
	£2,284,861,000

The figures are not strictly comparable because there was a change in the statistical method of dealing with publicly-owned goods, the complete figures for which have been included in the second half of 1917, while most Government goods except food were included in the first half of the year. During the whole period, 1914 to 1917, the value of our imports, as shown by the Board of Trade figures, exceeded that of our exports by £1,383,500,000; but, as already explained, this amount can be largely accounted for by freights and insurance charges which were ultimately received by this country. We made new loans to the Dominions and to our Allies during the war period amounting to approximately £1,500 millions, and, on the other hand, we borrowed moneys abroad or sold part of our investments abroad amounting together to about £1,900 millions.

Owing to the abnormally heavy adverse trade balance, the maintenance of the foreign exchanges, which was an object of the first importance for the finance of the war, was a matter of great difficulty. Towards the end of July, 1915, the American Exchange became increasingly unfavourable. Immediately after the outbreak of war it had been as high in our favour as 6, and as the normal gold parity is 4·8665 this represented a premium of 20 per cent. By April, 1915, it had fallen back to 4·86, and a slow but steady decline set in. On October 1st, 1915, the New York cable rate on London went as low as 4·50. This was primarily due to the exceedingly heavy payments which had to be made in New York for the British and Allied Governments. An Anglo-French Commission was then sent to New York and arranged for an Anglo-French loan of $500 millions. This measure did not prove adequate, and in December the Treasury announced that, with a view to facilitating the maintenance of the exchanges, the Treasury were prepared to purchase certain American and Canadian dollar securities owned in Great Britain, or to receive such securities on deposit. In the case of securities deposited on loan the lender was to receive all interest on dividends, and also by way of consideration for the loan an additional payment at the rate of half of 1 per cent. The scheme was subsequently extended to certain Japanese, Scandinavian and Argentine securities. These measures sufficed to maintain the exchanges throughout 1915, but not without wild fluctuations. In 1916 the movements were not so wide, and on the whole they were rather more favourable to this country, but owing to the increasingly heavy purchases abroad and loans to our Allies they gave further anxiety in the early part of 1917, and until America entered the war our position was unsatisfactory.

On October 31st, 1917, the Chancellor of the Exchequer stated in the House of Commons that "it was an open secret that before America had come into the war the method of financing our expenditure there and the question of exchange was not only a serious problem, but, so far as I was able to judge, it was an absolutely insoluble problem on any of the principles on which our finance had hitherto been carried on."

Owing to the financial arrangements which we were able to make with the United States Government the American exchange has been established on a satisfactory basis, but the neutral exchanges have moved against us. At the present time the sterling exchange, as measured in Swedish currency, has fallen about 23 per cent., and our exchange has been at a discount of 20 per cent. in Norway, 16 per cent. in Denmark, 9·5 per cent. in Holland, and 22 per cent. in Spain.

For the great majority of the people of the United Kingdom the outstanding financial feature of the war has been the rise in the cost of living. From the South African war down to 1905 wholesale prices showed comparatively trifling changes, and they fluctuated between 96 and 100, but in 1906 an upward movement began which continued almost without interruption until 1913. For the first half of 1914 there was a slight check to this advance. Immediately after the outbreak of war there was a considerable rise in the price of foodstuffs, but for the first five months the movement in raw materials was mainly downwards owing to the dislocation of trade. In 1915, however, practically every article advanced in a marked degree, especially in the later months of that year, when the abnormal freight situation was the dominant factor. The Board of Trade index number for forty-seven articles was 143·9 for 1915 as compared with 113·6 for January–July, 1914. The advanced continued throughout 1916, and was more pronounced than in the preceding twelve months, the index number for the year being 186·5. The upward movement continued at an accelerated rate in 1917, the index number for that year being 242·9. The advances in the prices of foodstuffs and raw materials since 1913 have been fairly approximate, although they have not been equal. The *Statist* index number shows that whereas in 1917 materials were 98 per cent. dearer, foodstuffs had risen 118 per cent.

There had been a widespread controversy as to the cause of the rise in prices and the effect of what is termed the inflation of the currency upon the course of prices. Professor Nicholson defines inflation to mean "an abnormal increase in the currency," and his conclusion is that "if the inflation of the currency continues the rise of prices will also continue."

The Select Committee on National Expenditure expressed the view that the chief causes of the increase in prices are :—

The expansion of credits during the war;

The demand for commodities exceeding the supply, and the inadequacy of Government action to control prices;

Increases of wages and consequent increases in the cost of production;

Increases in the rates of profit;

Unfavourable rates of exchange in some countries from which supplies are imported.

Some of these are at once effects of the increase of prices and causes of further increases.

The committee express the opinion that in the expansion of credit the issue of paper currency as hitherto practised in this country during the war plays a very subordinate part. If in any degree contractors' accounts had been met, or if the soldiers and sailors had been paid, simply by using the printing-press and issuing fresh supplies of currency for such purposes, the effect would, of course, have been serious. But this has not been done, and is not in contemplation. Notes are not issued in order to make Government payments. They are issued to meet requests from the banks for the currency needed by their customers; their quantity is regulated by those requests, and neither exceeds nor falls short of them; they have to be paid for by the banks by transfer of securities or in other ways. The amount of legal tender currency has largely increased. At the outbreak of war it is estimated that there was in circulation or in bank reserves about £222 millions. It is now calculated at about £338 millions, not including such small quantities of gold as may remain in the hands of the public. It is held, however, by the Treasury, that this increase is necessary in order to keep pace with the growth of transactions as measured in terms of money, and that it is a consequence and not a cause of the increased purchasing power of the community.

The Committee of the British Association on Credit and Currency issued a report in 1916 which contained an estimate founded on Mint returns of the pre-war amount of gold in the United Kingdom. The estimated amount at the end of June, 1914, was £161·1 millions, of which £82·8 millions were held by the banks

and £78·3 millions by the public. In effect, the gold formerly in the hands of the public has been withdrawn from circulation and its place has been taken by the currency notes. The total amount of the latter outstanding at the end of January, 1918, was £212 millions.

I am strongly of opinion that the rise in prices cannot be fairly ascribed to what is termed the "inflation of the currency." The advance is, I believe, entirely attributable to the war, which, on the one hand, produced intensification of demand, and on the other hand, an obstruction of supplies. This, coupled with the necessity of changing the character of the national production from a peace basis to a war basis, appears to me to entirely account for the rise in prices. As the prices of commodities advanced the amount of the circulating medium required to finance the trade of the country had to be increased to a corresponding extent. The rise in wholesale prices has amounted to 128 per cent., and the quantity of production has been well maintained, even if it has not been increased, and that we should have been able to finance such a gigantic war with an increase of currency of only 52 per cent. appears to me to be a magnificent tribute to the soundness of our financial and monetary systems. It is instructive to note that while our currency has increased by £116 millions, or 52·2 per cent. during the war, the paper money in circulation in the United States increased by £248 millions, or 46·4 per cent. In Germany the circulation of the notes of the Reichsbank increased from £94 millions to £573 millions at the end of 1917, an advance of £479 millions, or 509 per cent.

The belief appears to be generally entertained that the cost of living has increased by 105 per cent. since the outbreak of war, but Lord Rhondda stated (January 3rd, 1918) that the Board of Trade figures showing a rise of 105 per cent. were altogether misleading, for the cost had not gone up by very much more than 50 per cent., and during the last six months the actual cost had decreased by 10 per cent. People had had to alter their method of living, and were not consuming the same class of food. Lord Rhondda, however, omitted to state that the bulk of the decrease was due to the fact that the Government had allocated £45 millions for the purpose of reducing the price of the loaf to 9*d*.

It must be remembered that the increase in the cost of living is a world movement, and has not been by any means confined to belligerents. The *Labour Gazette* for August, 1917, and February, 1918, gave the following particulars as to the increased cost of living since August, 1914, in the countries referred to:—

1917.

Canada	(November) . .	63·1 per cent.
Switzerland . .	(March 1st) . .	57·3 ,,
Norway . . .	(March) . . .	82·0 ,,
Australia . . .	(February) . .	25·6 ,,
Italy	(end of April) .	63·9 ,,
United States . .	(October) . .	53·0 ,,
Sweden. . . .	(November) . .	99·6 ,,

The rise in prices and the consequent increase in the cost of living brought about a deep feeling of unrest throughout the country. It was believed that private interests were exploiting the needs of the populace, and that there was a vast amount of profiteering. Very exaggerated views appear to be entertained as to the extent to which profiteering has affected the rise in prices. At first it was said that the shipowners were the culprits, but on July 20th, 1917, Mr. Clynes (Ministry of Food) told the House of Commons that shipping rates had no important bearing on the cost of the principal articles of food. Later the farmers were accused of profiteering and holding up supplies, but no satisfactory evidence has yet been produced in support of this charge, and the public must ultimately recognise that one of the principal causes of the rise in the cost of food is the persistent demands of labour for increased wages. As the Select Committee on National Expenditure stated in their report: "Fresh cycles of wage advances succeed one another. Each one results in further increases of prices or in preventing a reduction of prices. An individual trade may obtain by a wage advance temporary relief from the increase in the cost of living, but only, as a rule, at the expense of all other trades. And the gain is short-lived, for the result is a demand from the others for similar advances, which raise the cost also of the commodities they produce. The producers are raising prices against themselves as consumers. Meantime the cost of the war is vastly increased. We are deeply impressed by the seriousness of the position in this respect, and are convinced that, if the process continues, the result can hardly fail to be disastrous to all classes of the nation."

After the outbreak of war employment became very acute, and before the end of 1914 a considerable amount of overtime was being worked, and in several trades complaint was being made of a shortage of labour. This was especially the case in engineering, shipbuilding, woollen, and

leather and kindred trades. Concurrently the prices of food and other necessaries rose. In the circumstances, the movement began in 1915 to raise wages. From March onwards it spread to nearly all the principal industries, and its effects have been far greater than those of any other upward movement in wages previously recorded. No complete account can be given of all the changes in rates of wages which have been made since the beginning of the war, as among the unorganised workers many changes escape attention, but it appears that up to the end of 1916 nearly six millions of workpeople received some advance. The average weekly increase was about 6*s.* per head. In 1917 a further great increase of wages took place, and 4,700,000 workpeople received advances of wages amounting in the aggregate to £2,200,000 per week (*Labour Gazette*, January, 1918).

On November 21st, 1917, Mr. Bonar Law stated that in the case of income tax assessed quarterly upon weekly wage-earners employed by way of manual labour, the following estimates might be given for the year 1916-17:—

Gross assessments	£202,000,000
Net produce	3,000,000
Number of wage-earners with incomes above exemption limit . .	1,500,000
Number of weekly wage-earners liable to pay tax after deduction of the statutory abatements and allowances	630,000

Taking the whole of the employed people of the United Kingdom, I estimate that the wages bill for 1917 was between £500 and £600 millions more than in 1913.

As a result of the pressure of public opinion, a Ministry of Food was created at the end of 1916. The duties of the Minister, according to the Act, are "to regulate the supply and consumption of food in such a manner as he thinks best for encouraging the production of food." The Ministry set itself to control all foodstuffs, with a view to making them accessible to the community in equitable shares and at reasonable prices, and to limit the profits derivable from all transactions and sales relating thereto, and to reduce the cost of necessaries as far as possible. It accordingly brought all the principal foodstuffs under control, as well as a number of subsidiary foods. The stupendous task of regulating the nation's food at a time of restricted supplies was naturally not accomplished without friction and difficulty. An important step in decentralisation was taken in the appointment of local food committees with considerable powers over prices and distribution, and there are now about 2,000 of these committees at work.

In the autumn of 1917 the campaign for voluntary rationing was inaugurated, but it did not meet with any great measure of success. The food position became somewhat acute at the beginning of 1918, when the meat shortage was severely felt and there was a great scarcity of butter, and by the middle of February a compulsory system of rationing was well on the way. On the whole, however, it may be fairly claimed that during the first three and a half years of war the great bulk of the people of the United Kingdom were as well, if not better, fed than in time of peace, and they were certainly better off in the matter of food than any of the other belligerents, with the exception of the United States.

I have now completed my rough survey of the manner in which the resources of Great Britain have been organised for war, and I hope, notwithstanding its incompleteness, it is an impressive picture. A number of people are so busily engaged in finding fault with matters of detail that they have failed to envisage the national achievement as a whole. It is true that many ludicrous and sometimes tragic mistakes have been made. We had to find, by bitter and costly experience, the directions in which our strength could best be developed; but it is now possible to perceive that under the driving force of public opinion, and in accordance with that capacity for adaptation and improvisation which is one of our greatest national attributes, the task of mobilising all our resources for the purposes of the war has been accomplished with the utmost completeness and efficiency.

Happily, we started the war with an immense mercantile marine and a great and efficient navy. As history has proved time after time, sea-power is our real source of strength. It enabled us to put all the national effort into the building up of the Army and the Air Service. These tasks have been achieved at some sacrifice of sea-power, but we are now, in a measure, free to devote ourselves to the building up of our mercantile marine, and there can be no doubt that this will be done with true British thoroughness.

Great as has been our achievement in the past three and a half years, a wider and even more difficult task awaits us in the immediate future; but the splendid patriotism and the power of organisation of the British people as a whole inspire the confident belief that we

shall overcome the difficulties of demobilisation, and reorganise our industrial life in as complete and efficient manner as we have organised for war.

POWER FROM VOLCANIC STEAM.

In the barren, desolate region in the vicinity of Volterra, in south-western Tuscany, are a great many fissures or cracks in the earth's surface, from which small clouds of steam arise, evidently of subterranean origin. Almost a century ago a Frenchman, François de Larderel, visited this region and made an analysis of the steam. He discovered that it was heavily charged with boracic acid. Beginning at the Poggio Casa la Serra, extending south over the summit and down the valley of the River Cornia, he found numerous fissures from which steam arose. Selecting the largest of these, at what is now the town of Larderello, about fifteen miles due south of Volterra, he established a plant for the extraction of boracic acid, which was the beginning of what is now a most successful industry.

In the present plant the vents are covered, the steam condensed by the air as it reaches the surface, and the resulting water is led in open wooden troughs into shallow pans, where, by the aid of certain precipitates and evaporation, boracic acid in crystalline form is obtained. These pans, lined with lead, about 6 ft. by 4 ft. and 4 in. deep, are in sets, and arranged in steps on the slopes of the hill, so that the water, delivered by troughs into the highest pan of each set, drains through each pan of the series, and finally into a tank or vat. As evaporation proceeds, crystals of boracic acid are deposited along the edges of each pan, the edges being flattened and sloped so as to facilitate this process, from which they are gathered and taken to drying rooms and spread out on shelves to hasten drying. Both evaporation and drying have been assisted by the installation of pipes, much in the manner of steam-heating pipes, the steam used being obtained from the earth fissures. Steam from the same source is used to heat the offices of the company and the houses of the employees.

Several years ago, writes the United States Consul at Florence, it was decided to use some of the surplus steam from the fissures to operate a small horizontal engine. This was installed and used to furnish the small amount of power required for various purposes in the works, and is still used as occasion demands.

When the low-pressure steam turbine was invented, it was seen that it might be possible to use this steam as a source of power. Vents were selected, borings made, and it was found that no diminution of pressure resulted when the borings were made a sufficient distance apart, about 50 ft. to 100 ft. Holes were then made to a point where a pressure of from two to three atmospheres and a temperature of from 150° to 190° C. could be obtained from the steam. The power thus obtained was utilised for the production of electric energy, which could be transmitted to neighbouring towns. Additional capital was invested and a modern electric plant erected. Piped borings were made into the earth, from which the steam is carried to tubular boilers. As the steam is highly impregnated with boracic acid, the tubes are of aluminium outside. The steam is applied to these tubes, and the heat from it used to turn pure water, obtained from other sources, into steam, which, in its turn, operates the engines connected with the dynamos. There are installed at present three groups of alternating turbines of 4,000 h.p. each producing from the dynamos a three-phase, 50 period, 4,000 volt current. The current is transformed into 16,000 volts for transmission to Volterra, Saline di Volterra, Pomerance, Castelnuovo, and Monterotondo, all neighbouring towns. Current at the same voltage is delivered to the Società Maremma di Elettricita, which delivers it as far as Follonica, on the west coast. For the two large customers—the Società Elettrica Mineraria del Valdarno and the Società Ligure Toscana di Elettricita—the voltage is increased to 30,000 and 40,000, the direct line for the first going by way of Colle d'Elsa, above Sienna, and the Central of Castelnuovo, while that for the second goes by Cecina, on the west coast, and Castiglion Cello to the Central at Leghorn.

The company known as the Società Boracifera di Larderello has its offices in Florence, and is controlled there. On a capital of 5,645,000 lire, dividends at the rate of 5 per cent. per annum are paid. Apart from the power produced, it is stated that 2,537 tons of crude boracic acid, 839 tons of refined boracic acid, 1,164 tons of borax, and 55 tons of carbonate of ammonia, were produced in 1914. The steam is strongly impregnated with sulphur in one of its various forms, but this is eliminated when the steam reaches the open air.

SCIENTIFIC RESEARCH IN AGRICULTURE.

The President of the Board of Agriculture (Mr. R. E. Prothero), in the House of Commons on July 18th, reviewed the operations of his department during the past twelve months. After alluding to the work of Professor Russell at Rothamsted, in connection with the turning of grass land into arable, and the production of an effective soil insecticide, and of Professors Wood and Hopkins at Cambridge, on animal nutrition, he illustrated the possibilities of scientific research in agriculture from Professor Biffen's well-known plant-breeding investigations. He pointed out that, after examining a number of varieties of foreign wheat, Professor Biffen discovered a Russian wheat called ghirka, which resists rust. Now rust destroys annually thousands of quarters of wheat, but this ghirka wheat was of no use to the British farmer because its yield was miserably low. But Professor Biffen, by using the Mendel

system, was able to transfer the rust-resisting quality of ghirka to a high-yielding English wheat, and though that wheat has now been in use for several years, it has shown no tendency whatever to revert either to the rust tendency of one parent or the low-yielding tendency of the other. He has now produced a wheat which produces a high quality of straw—a fine, stiff, upstanding straw—and a high quality of yield of grain, so much so that without pushing it will produce forty-two bushels to the acre, and by pushing, up to seventy-two bushels to the acre. It also possesses a very high quality of disease resistance, which is so highly valued by both millers and bakers, and which is recognised in increased prices.

Mr. Prothero added: "Hitherto the plant-breeding work has been hardly applied to any of the crops of the farmer except wheat—though it has been applied partly to barley—and mainly to wheat suited to the Eastern Counties. But suppose you apply it to the wheats and barleys used in other districts, to oats and rye, to temporary grass and potatoes. There is an extraordinary list of possibilities opened to the British farmer. If, for instance, you could produce a potato which was immune from blight and immune from wart disease, it would be an invaluable boon to English agriculturists, and there is every prospect that that may be achieved."

THE INDIAN HIDE TRADE.

Sir Henry Ledgard, in the important paper he read before the Indian Section of the Society on February 14th, referred to the capture of this large trade by the Germans before the war. He declared that in the background there are still the old ring firms or their successors, resenting their present exclusion, agitating for recognition, bringing pressure to bear upon Government, trading with neutrals, "and ready to pounce upon the trade (of which they had the monopoly) directly peace is declared and the Continental market reopens."

In the House of Commons, on July 10th, Mr. Montagu, Secretary of State for India, said the statement that before the war the East India export trade in raw hides was largely in the hands of, and controlled by, the Calcutta Hide Trade Association, which worked with a Hamburg association, and by its methods virtually maintained a monopoly, was, he believed, substantially correct. The Calcutta Hide and Skin Shippers' Association consisted of seven firms, of which five had been wound up under the Enemy Trading Act, while from the remaining two enemy interests had been completely eliminated. He had ascertained from the Government of India that there three alien employees (two Swiss and one Italian) of liquidated firms had started business. The export trade in raw hides was now controlled by the Government of India, who, on behalf of his Majesty's and the Italian Governments, purchased the exportable surplus of certain classes. As purchasing agents five British or Indian firms were employed, but other firms, including the two reconstructed firms and the three new alien firms referred to, were permitted to participate in the export trade of hides not required by Government. They did not, however, in any sense enjoy a monopoly of such trade. The Government of India had the future regulation of this trade under consideration. The measures already adopted had done much to divert this trade to British and Indian merchants, and there was every reason to think that the enemy control of this important trade had been permanently eliminated. Asked if Mr. Howeson (late Ernsthausen) was not now occupied in getting back a considerable portion of this trade into German hands, Mr. Montagu said he could not carry in mind the details of the action of any particular individual, but he knew the Government of India were determined that any such efforts as suggested should not be successful.

NEW INDUSTRY IN GLASS-WOOL AND COTTON.

Spinning glass for commercial uses is an important new industry which has been developed in Venice within the past two years. The spun glass is marketed in three forms—hanks of spun glass thread of straight fibre called "Cotone di Vetro" (glass cotton), masses of spun glass curled fibre called "Lano di Vetro" (glass wool), and either of the above qualities pressed into sheets or pads from one-quarter to one-half inch in thickness that resemble white felt pads.

At present, writes the United States Consul at Venice, the principal use made of this product is for insulation, and especially for making separators for accumulators of electricity, but the glass wool would serve admirably for making artificial hair, wigs, perukes, doll's hair, Santa Claus beards, and other purposes, and in the pad form it serves as a hygienic filter.

The processes of manufacture are simple. Solid glass rods, about 2 ft. 6 in. long and the thickness of a lead pencil, are made of pure America soda that contains no adulteration of lead or other metal. The absence of lead and adulterations gives the quality of perfect flexibility to the fibre, and the best soda used in its manufacture comes from the United States, although an inferior kind was before the war obtained from France. On a simple desk is mounted a Bunsen burner or gas flame and blowpipe. By the side of the desk is mounted an ordinary bicycle wheel minus the rubber tyre, that revolves rapidly and regularly at rhythmic speed under power furnished by a small electric motor. A motor of 2½ h.p. will operate fifty or more wheels.

A girl sits at the desk, melts the end of the glass rod in the flame of the gas burner, draws it to a thread and throws the thread around the wheel. If the thread breaks, she must repeat the process; if not, she slowly revolves the end of the rod in the constant flame, and it is automatically spun to

a very thin filament. The hank of thread on the wheel, when it has assumed the dimensions of a bicycle tyre, is taken off. Separated with the fingers, it curls and fluffs out like wool if the thread is sufficiently fine. It is packed in the hank as glass cotton, in the fluff as glass wool, and in the compressed form as glass wool or cotton according to the fineness of the fibre.

The cheaper grades of spun glass formerly came from Germany. It is claimed that the Italian article is superior owing to the purer soda used.

ENGINEERING NOTES.

Concrete Chimney in Japan.—Particulars of a very high reinforced concrete chimney which has been completed in the last few months for a smelter plant at Saganoseki, Japan, are given in the *Engineering News-Record*. It is 570 ft. high, 42 ft. 8 in. outside diameter at the bottom, and 26 ft. 3 in. inside diameter at the top, with a thickness of 29½ in. at the bottom and 7 in. at the top. The design includes provision for earthquake stresses, and was checked and approved at the Imperial University of Tokyo. The foundation is a huge block of monolithic Japanese portland cement concrete, in the form of a truncated cone 17 ft. high, 95 ft. diameter on the base, and 42 ft. at the top. The centre portion of the top is concave, with a bottom thickness of 7 ft. This foundation contains 2,711 cubic yards of concrete, and required thirty days' work, day and night, for its construction. The pressure on the base is about 6,000 lb. per square foot, including allowance for wind pressure. The steel reinforcement in the foundation and chimney amounts to 530 tons, and consists of plain round and square bars of American make, purchased in Japan. The lightning-rod protection is quite extensive. At the top is a copper circle, with seven platinum points extending 4 ft. above the edge of the chimney. From this circle seven cables lead down the chimney. At a height of 400 ft. from the base is another copper circle, or circuit, with four platinum points, and from it four rods lead down to the base.

Rust Preventive.—A new rust-preventive remedy, recommended for small machinery parts, is, says *Ice and Cold Storage*, an application to the surface of the iron or steel of iron phosphates. After thoroughly steaming, the articles are immersed in a little bath containing ferric and ferrous phosphates, with a little manganese dioxide, and at boiling-water temperature they are left until hydrogen is no longer given off. The articles are then air-dried, when they may be treated with mineral oil, or painted, japanned, or otherwise finished. As the phosphate surface is attached chemically to the metal, no rust forms even in cracks in the paint.

Victorian Water Storage Schemes.—According to a statement issued by the Water Commission, says the *Indian and Eastern Engineer*, twenty-four sites have been inspected in the Upper Murray Valley for a suitable place to erect a large storage reservoir in connection with the Murray water scheme. The only site considered suitable is one about ten miles above Albury, just below the junction of the Mitta Mitta and Murray Rivers, and between the end of the Table Top Range in New South Wales and the end of the range between the Mitta and Kiewa valleys in Victoria. To provide storage here, holding 1,000,000 acre-feet of water, the barrage would be 4,000 ft. in length and 70 ft. in height above the level of the flats. Should the necessity arise at any future time to double the capacity of this proposed storage, the Water Commission states that it could be done by raising the barrage 30 ft.

South African Iron.—Dr. Wagner, in his presidential address to the mineralogical section of the South African Association for the Advancement of Science, announced that four small blast furnaces are being installed for the purpose of smelting the rich titaniferous iron ores of the bush veld, of which it is estimated 300,000,000,000 tons are available. Cheap Transvaal coal would be used, and Dr. Wagner stated that, if the experiment were successful, South Africa would eventually be able to export iron and steel, and to compete with the leading iron-producing countries.

Katanga Railway.—The recent completion of the section of this line to Bukama, says the *Railway Gazette*, on a navigable portion of the Upper Congo River, represents an important addition to the line between Cape Town and Cairo. There is the further promise, now that the Suez Canal has been bridged, of forging a rail between the African and Asiatic railway systems. The completion of this project would involve the construction of a large mileage of railways, and there is also the difficulty of break of gauge to be overcome.

Rhône Canal Scheme.—The importance of this scheme was the subject of a lecture delivered on behalf of the Nouvelle Société Helvétique at the Steinway Hall, by M. J. Valloton. He said that as soon as peace conditions are restored, the Germans will open the Rhine for commercial traffic, with the inevitable result of drawing Switzerland into the arms of Germany, and subjecting her to a complete economic servitude in the interest of Mittel-Europa, unless immediate steps are taken to counteract a tendency so harmful to the economic interest of the Allies, by making the Rhône navigable between Geneva and Lyons, thus giving Swiss commerce direct access to the Mediterranean. By this route Switzerland could obtain, besides coal, all the raw materials and colonial products which are necessary for her existence. All that is necessary is to make about twenty miles of the Rhône navigable by building

a lock at Genissiat, a work which, moreover, would put into use an hydraulic force of 300,000 h.p., capable of supplying Paris and the towns bordering on the Rhône with all the electricity which they could possibly use. The French Government has appointed a committee to go into the whole matter.

NOTES ON BOOKS.

THE MANUFACTURE OF INTERMEDIATE PRODUCTS FOR DYES. By John Cannell Cain, D.Sc. London, 1918: Macmillan & Co. 10*s*. net.

Modern dye materials, although there are exceptions, may be regarded broadly or generally as synthetic products, and, what is more, the synthetic dye-stuffs are, for the most part, end results of a long chain of intermediate stages, of which chain each link is a definite chemical compound. Thus it is that the synthetic dye industry has called into existence a new vista of organic compounds based on benzene as a more or less remote ancestor, these new organic compounds having been to a considerable extent called into existence in the quest for dye-stuffs. Incidentally, however, no small number of the intermediates thus called into existence, or their collaterals, have found valuable applications in other directions, as, for example, in photography and in medicine, and now possess definite importance in the world's work, quite apart from the dye industry.

Hence it is that the manufacture of the synthetic colours of our time is mainly and chiefly the manufacture of intermediate products; indeed, so much is this the case, that the colour manufacturer does not in all cases supply an actual finished colour, but instead he supplies intermediates, which are not dyes, but which the dyer so uses as to produce the required colours on the textiles or the yarns.

In this aspect of the case it may not be too much to say that Dr. Cain's book now before us is, in the fundamental sense, a much more real handbook of aniline colour manufacture than many in which the actual production of the colours is explained. The intermediates being in hand, the production of the colour is often an operation parallel in simplicity with Béroalde de Verville's mode of making slippers by cutting down a pair of boots.

In his book of 264 pages Dr. Cain deals satisfactorily with the three or four hundred intermediates which are essentials in the aniline colour industry, and in the really best sense of the term we may say he deals "fully" with this large number of products, as in addition to such particulars as it is practicable to include in the book, our author gives reference to every original source, although he expresses a doubt as to whether any single library in England contains the whole of the literature which is involved; but he has done his best to obviate the necessity of making reference to the original sources. This best is a very good best, and may be regarded to a considerable extent as an outcome of Dr. Cain's experience as editor of the *Journal of the Chemical Society*, there being nothing in the book which borders upon padding or "fill-up," and it is assumed that the reader has a good general knowledge of the chemistry of the aromatic series; hence the symbolic representations are not given in full, the benzene ring itself not being lettered. Further, there is no description of quite ordinary or everyday plant or appliances, but everything quite special to the operation is fully described and well illustrated. Again, the reader is often told to use the theoretical or equivalent quantity of a reagent. This conciseness detracts nothing from the real usefulness of the book, and enables the author to include far more than would otherwise be the case.

Dr. Cain can, however, be detailed, and even diffuse, where there is good reason for such a course, this being notably so in the section on aniline, pages 39–46. In this section aniline is not only aniline itself, but the typical amino-body of the aromatic series. Hence the student will find noted all those various modes of reduction of nitro-benzene which may have escaped the notice or knowledge of even mature chemists, who pride themselves on keeping thoroughly current. We may instance the reduction of the nitro-benzene by free hydrogen or by carbon-monoxide and steam, or by water gas, an appropriate catalyst being used in each case. For example, nitro-benzene vapour and hydrogen mixture reacts at 230° C. when poured over pumice coated with silver, or at from 230° to 250° when gold is the catalyst; but hydrogen and steam, if passed through nitro-benzene and then over finely-divided nickel, give an almost theoretical yield of aniline at low temperature.

The vacuum still for aniline is well detailed and illustrated.

So useful and thoroughly satisfactory a book will be alike welcome to manufacturer and student, and we may, perhaps, venture to predict a rapid growth in future editions. In any case, we may congratulate the author on having done something notable towards that revival of the aniline colour industry which we hope to see in Great Britain.

PRACTICAL ORGANIC AND BIO-CHEMISTRY. By R. H. A. Plimmer. New and Revised Edition. London, 1918: Longmans, Green & Co. 18*s*. net.

Our rather full notice of the original edition less than three years ago (*Journal of the Royal Society of Arts*, December 31st, 1915, page 134) makes it necessary to do but little more than call attention to the new and revised edition.

All the good features of the original edition characterise the present volume, with the advantage of revision and bringing up to date. General organic chemistry is well summarised in the 636 pages, and, as the title suggests, some emphasis is

laid on compounds and reaction concerned in the vital processes. The section on the analysis of tissues (pages 573–604) treats of the matter briefly as affecting inorganic constituents, and as regards organic constituents very fully and thoroughly, not only from the qualitative aspect, but also the quantitative, special consideration being given to those details and dates which assist in identification and determination where small quantities are concerned (micro-analysis).

Plimmer's "Practical Organic and Bio-Chemistry" has, by reason of its special merits and qualities, already taken up a standard position.

FITZHANGER MANOR, Ealing Green. By Arthur T. Bolton, F.S.A., F.R.I.B.A. Sold at the Soane Museum. 7*d*.

Fitzhanger Manor, which is now the Ealing Public Library, was from 1800 to 1811 the country retreat of Sir John Soane. This brief account of it has been written by the Curator of the Soane Museum, who suggests that a study of the building will be helpful as illustrating the origins and development of Soane's artistic ideas. Soane was an architect who planned a large number of important buildings. His notions were by no means conventional, and in his time he met with much hostile criticism and even ridicule. In view of this it would have been interesting to have fuller descriptions of Fitzhanger Manor than Mr. Bolton has given us, but the photographs are excellent.

The Soane Museum itself, in Lincoln's Inn Fields, is not nearly so well known as it ought to be. It contains a remarkable collection of works of art, antiquities, books, gems, illuminated manuscripts, and architectural designs which Soane himself formed for the benefit of his own and other students. The museum should possess a special interest for Fellows of the Society, which appoints one of the trustees.

GENERAL NOTES.

THE PRODUCTION OF DIAMONDS.—The Bakerian Lecture at the Royal Society was delivered by the Hon. Sir Charles Parsons, K.C.B., F.R.S., on "Experiments on the Production of Diamond." The paper alluded to some of the results of experiments described in papers by the author to the Royal Society in 1888 and 1907, more particularly those on the decomposition by heat of carbon compounds under high pressure, and on the effect of applying pressure to iron during rapid cooling. A description was given of experiments designed to melt carbon under pressures up to 15,000 atmospheres by resistance heating and by the sudden compression of acetylene oxygen flame, and by the firing of high velocity steel bullets through incandescent carbon into a cavity in a block of steel. Allusion was made to experiments on chemical reactions under high pressure and their results. The pressures occurring in rapidly cooled ingots of iron, and experiments bearing upon this question, were discussed. Experiments at atmospheric pressure and experiments *in vacuo* were described. The main conclusions arrived at were that graphite cannot be converted into diamond by heat and pressure alone, within the limits reached in the experiments; that there is no distinct evidence that any of the chemical reactions under pressure have yielded diamond; that the only undoubted source of diamond is from iron previously heated to high temperature and then cooled; and that diamond is not produced by bulk pressure as previously supposed, but by the action of the gases occluded in the metal and condensed into the centre on quick cooling.

PROPOSED CANAL FROM GENOA TO LAKE MAGGIORE.—Attention is drawn in the *Geographical Journal* to a scheme propounded by Professor Baggi, of Turin, for constructing a canal from Genoa to Lake Maggiore. It is described, with a sketch-map and section, in *Navigazione Interna* (Milan). Professor Baggi proposes to cross the mountains on the direct line between the two termini by a tunnel twelve kilometres in length. This enables the canal to cross the watershed at a maximum elevation of 250 metres. A calculation of the water required to operate the canal, and of the supply available above the summit-level from the streams descending the inner versant of the mountains, shows that these would amply suffice for the needs of the canal and for all other purposes. The cost of making the tunnel is estimated at 7,000,000 lire per kilometre. After crossing the Lemme on the north side of the watershed, a second short tunnel would take the canal into the basin of the Scrivia, the further route being by Tortona to Bassignana on the Po, and thence nearly due north to Ticino below Lake Maggiore. Aqueducts would be required for the crossing of certain valleys, but would be of no very great length in the aggregate.

MAT-MAKING IN HOLLAND.—For more than a century the making of mats from bulrushes and other varieties of rushes has been a house industry in the province of Overyssel, along the Zuider Zee, from which the province extends eastward to the German border. Men, women, and children are engaged in the work, which, however, seems to be poorly paid, as it is stated that the earnings are only 1*s*. to 1*s*. 6*d*. per day. Before the war large quantities of mats were imported from Germany. This having ceased, mat-making in Overyssel has greatly increased. In districts along the Zuider Zee, writes the United States Consul at Amsterdam, the industry is conducted largely for the purpose of freeing swampy lands from rushes, so that they can be drained and made arable. Much good farm land has thus been produced, particularly in recent years, since companies and municipalities have taken charge or supervision of this industry.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

RECONSTRUCTION AND THE REAL COST OF THE WAR.

By Edgar Crammond,
Late Secretary of the Liverpool Stock Exchange; Managing Director of B.S.T. Limited.

Lecture III.—Delivered March 4th, 1918.

In my two preceding lectures I have given brief summaries of our economic position before the war, and the principal changes which occurred during the first three and a half years of war. I now propose to discuss the real cost of the war and the problem of economic reconstruction.

Many people are attempting to measure the gulf which three and a half years of war has created between our pre-war economic system and the position in which we find ourselves to-day, and to form some conclusions as to the conditions which will probably obtain after the war. In my opinion, the old economic system, if we could be said to have had a system, has gone for good, and we could not return to it even if we wished to do so. The conditions of international trade have been profoundly modified. Women have proved their industrial capacity, and will not go back to pre-war conditions, while the Reform Bill, which will double the present electorate by adding 2,000,000 new men voters and 6,000,000 women, of whom 5,000,000 will be married, is destined to effect an enormous influence upon the political and economic life of the United Kingdom.

Our pre-war economic policy served us well. It increased production, it brought us a very large measure of prosperity, and it laid the world under tribute to us; but it was a subconscious growth, and it had grave defects which were becoming manifest in the form of labour unrest. We have been told on competent authority that if the war had not broken out there would have been an industrial revolution in this country. Women who were not employed were restless and dissatisfied. Production was looked upon too much as a source of profit, and not as a service to the whole community. Our internal trade was subjected to violent fluctuation, it was open too much to foreign exploitation; there was great irregularity in employment, and there was a want of co-ordination in the various efforts of the nation.

Ordeal by battle has shown the weaknesses of our old economic policy as well as its advantages. For centuries it was our practice to throw out from the centre, as it were, our different sources of strength. In pursuance of this policy we encouraged our people to emigrate to the remote parts of the world. We invested an immense proportion (practically one-fourth) of the national wealth outside the limits of the United Kingdom. We became the citadel of the international monetary system, and we opened our money markets to the whole world. Our investments abroad have proved of inestimable value during the war. They have been our real war treasure, and without them it is difficult to believe that we should have been able to finance our Allies and provide for our own expenditure. Under our Free Trade policy agriculture declined, and, as Mr. Prothero has pointed out, the factory and the furnace flourished by the ruin of English agriculture. But the greatest advantage we derived from our Free Trade policy was the development of British shipping. When the war broke out we owned one-half of the mercantile tonnage of the world, and it was the magnitude of our mercantile marine, and the fact that through its use we were able to call upon not only the Empire but the whole world for supplies of food and raw materials, that saved the Empire and our Allies from disaster.

The general tendency of our economic policy was to subordinate everything to the development of international trade and finance. The amalgamation of the joint-stock banks resulted in the draining of a large part of the liquid capital of the country to London, where it was employed in financing, carrying, and insuring world trade. The Stock Exchange, Lloyd's, and all the other great financial institutions, were engaged primarily in the development of world trade, rather than purely United Kingdom trade, although, of course, the one reacted on the other. We threw down all the barriers which restricted the freedom of commerce, and we became dependent upon foreign countries for more than half our supplies of foodstuffs and raw materials. At the same time, we allowed ourselves to become dependent upon Germany for supplies of commodities which were vital to the conduct of some of our greatest industries.

Germany, on the other hand, pursued an economic policy of centralisation. Notwithstanding the vast growth of her population during the past forty-five years, she, by means of the intensive development of her agricultural industry, became to a large extent self-supporting in the matter of food supplies. For many years she set her face against the emigration of her people, and it is only within a comparatively short period that she attempted to carry out a policy of colonial expansion.

The final purpose of economic labour is production to meet consumption, and I venture to think that in the past we paid too much attention to production and too little attention to consumption. There was waste in the production and consumption of food. The report of the Food (War) Committee of the Royal Society (Cd. 8421) showed that the amount of food produced and imported into the United Kingdom during the period 1909–13 was 15 per cent. in excess of the amount required to feed the entire population, and yet there is irrefutable evidence that a large proportion of the population was under-nourished. Then our industrial organisation was defective. There was waste in the production, consumption, and distribution of coal and motive power. "The present coal consumption would, if used economically, produce at least three times the present amount of power."* The Coal Controller estimates that, by bringing the consumption of coal as nearly as possible to the source it will be possible to save, roundly, 700 million ton-miles per annum. Again, we did not make the most economical use of our shipping. Under war conditions the carrying power in weight per 100 tons net of shipping entrances increased from 118 tons in 1914 to 143 tons in 1916.* (This latter result was largely brought about by the substitution of tramps for the big passenger steamships.)

Undoubtedly, a large number of people were engaged in services which were not essential to the national welfare. There were too many people employed in distribution and too few employed in production. The drink traffic was not sufficiently controlled. There were too many domestic servants, too many chauffeurs; and anyone who will take the trouble to examine closely the reports made under the Census of Production Act cannot fail to be impressed by the smallness of the national output in relation to our capacity to produce. The great industrial nations of the world were unsettled, and there was a growing feeling of anxiety to secure future supplies of foodstuffs and raw materials. The more progressive nations of the world were being transformed too rapidly from agricultural production to manufacturing production.

Paragraph 82 of the final report of the Dominions Royal Commission states: "During our journeys throughout the Empire we have been impressed by the fact, which is general in the world and which is not confined to any particular epoch, that the industries engaged in the utilisation of the land are less remunerative than city trades and the occupations of middlemen and merchants. Too much of the profit appears to go to the distributing interests and not enough to the primary producer. This tends to concentrate people to an undue extent in large cities and to withdraw them from country districts where their presence is most needed. Apart from the financial attraction of the city, life there presents greater amenities and greater excitement than do agricultural and pastoral pursuits. No universal remedy can be suggested, but we hold that everything which conduced to keep an adequate proportion of the population engaged upon the land or in country pursuits, everything which increases the attraction of agricultural life, should be regarded as beneficial to the development and strengthening of the community."

"Everywhere throughout the Empire we have been met by the complaint, to the accuracy

* Reconstruction Committee, Coal Conservation Sub-committee (Cd. 8880).

* Annual Report of the Liverpool Steam Ship Owners Association for the year 1916.

of which our own observation has testified, that the population is not inclined to settle on the land, or, if it has settled there, shows a strong tendency to leave it for the cities. Thus in Australia more than half of the total population, already small enough for so vast a continent, dwells in a few towns, nor is there any sign at present that these undesirable proportions are in course of change."

The question for us now to consider is what should be the lines of national economic development and what should be the national trade policy of the United Kingdom in relation to the rest of the world. In order to clear the ground for the consideration of these problems it will be well to deal first with the question of the real cost of the war and the reconstruction of the national finances.

From statements made by the Chancellor of the Exchequer on moving the fourth Vote of Credit, it may be assumed that the gross amount of the National Debt on March 31st, 1918, will be, approximately, £6,000 millions.

From this we are entitled to make the following deductions :—

	Millions. £	£
Loans to Allies and Dominions, including liability undertaken by India	1,500	
Less estimated amount of Loans to Allies which may be irrecoverable, say	500	1,000
Unsold Stocks in Ships, Raw Materials, Foodstuffs		250
Arrears of Excess Profits Duty		200
Value of Munition Works, Lands, etc., say		500
		1,950
Estimated net debt at the end of March, 1918		4,050

To this must be added the cost of carrying the war to a conclusion and winding it up, including demobilisation and the thousands of items which will have to be paid.

Demobilisation alone will probably take two years to accomplish, and it is estimated that during the first 12 or 18 months it will involve an expenditure of £2 millions per day. The winding-up of the war may therefore be estimated to involve a further net addition of at least £2,000 millions to the National Debt. But we cannot simply discharge these glorious men and leave them to find occupations for themselves in what may prove to be an overcrowded labour market. Justice and expediency demand that we should provide them with both adequate capital and adequate opportunities for employment. The very minimum we can fairly do is to place to the credit of every man who has served three years in the Army or the Navy a sum of £100, with safeguards which will provide that the money shall not be squandered. The aggregate sum required to pay this bounty will add £400 millions to the National Debt.

It may be objected that it is taking too sanguine a view of the situation to deduct from our war debt the whole of the amount which we have advanced to our Allies, and I therefore propose to omit the £500 millions which we have advanced to Russia.

If the course I have outlined above should be adopted, the total amount of the National Debt at the end of the war should be about £6,500 millions, exclusive of the capitalised value of pensions. How much of this vast sum can be truly described as lost? Only a comparatively small proportion, viz., that which has been borrowed abroad. I am in complete agreement with the following views, which were expressed many years ago by Sir Robert Giffen on the subject of the National Debt.

In his "Essays on Finance," First Series, Giffen said: "The National Debt is a mortgage upon the aggregate fortune of the country. As we may assume it to be practically all held at home we may reckon upon our whole estate without deducting the debt, whereas we should have to deduct it if it were held by foreigners; but while we do not deduct the debt from the total of our estate, neither can we add it without falling into error."

He emphasised this in 1889 in his book on the "Growth of Capital," and added: "Of course to each individual holding a portion of the National Debt, the holding is property . . . On the whole the reason assigned is a good one, but I should not censure very much any one who included the debt as a part of the capital of the community . . . the money expression of all the other capital of the community is less than it would otherwise be by the amount of the debt . . . if there were no debt, lands, houses, etc., would exchange for rather more than they do now. The debt in this view represents a certain distribution of part of the capital of the country, and we do not get a complete view of the capital unless we include it."

The National Debt at the end of the war will probably be in the neighbourhood of 40 per cent. of the amount of the national wealth before the war, and the vast amount which must be raised annually by way of taxation to pay the interest, even though the Debt is practically all held at home, somewhat weakens the complacent views which Giffen took when the National Debt was

only about 4 per cent. of the national wealth.

The real cost of the war may be summarised under the following headings: The death and disablement of, say, one million men. Human suffering and sorrow cannot be expressed in terms of money, but if an actuarial valuation had to be made this million of lives might be estimated to represent £800 millions. On March 6th, 1917, the Pensions Minister (Mr. Barnes) informed the House of Commons that the number of persons under the charge of the Ministry at that date were as follows: Disabled men, 157,544; widows, 62,796; children of the widows, 128,294; dependents of deceased men, 29,832; widows who had not reached the pensions stage, 125,000; men in hospital, 65,000; medically unfit, 65,000; total, 633,466. The Minister added that there were 300,000 people who would benefit by the new Royal Warrant, making the total number of persons who would come on the books of the Ministry 1,000,000. The scheme in its entirety, would, he said, involve a capital charge of £396,000,000, and in the first year £25,000,000. On March 26th, 1917, Mr. Barnes announced that at that time £72,000,000 was being distributed throughout the country by way of separation allowances and pensions. Under the new Warrant a further £26,000,000 would be distributed, making, in round figures, a total of £100,000,000.

Then we have diminished stocks of food supplies, raw materials and manufactured goods. We have a large diminution in our shipping tonnage and the remainder of our mercantile marine is not in such an efficient condition as it was before the war. Then we have parted with a considerable proportion of our investments abroad. In the years preceding the war we used to invest about £200 millions abroad and expend about £200 millions in the form of new investments in the United Kingdom, besides providing about £180,000,000 per annum for depreciation, renewals, etc. This latter provision has been largely suspended during the war. The community is poorer to the extent to which it has been deprived of many services, such as cheap and frequent train services, shipping services, etc., but this is largely a temporary loss and cannot be expressed in terms of money.

Altogether I think it would be a reasonable estimate to assume that, including the capitalised value of the war pensions and the moneys borrowed abroad our real loss during the war is in the neighbourhood of £2,000 millions, but against this must be set the increased power of production.

If we should finish the war with a National Debt of £6,500 millions, what is our National Budget likely to be? We should have first to provide, say, 5 per cent. for interest and sinking fund, which would mean an annual charge of £325 millions.

Before the war the Civil Government cost £97 millions per annum. We are committed to a large and expensive scheme of educational reform, and we know that old age pensions will cost £18,000,000 instead of £12,000,000. The recent increases of salaries in the Government Departments will involve a large annual sum, and on the whole it would be prudent to reckon that in the first years of peace the cost of Civil Government will not be less than £150 millions, while pensions will call for an annual provision of at least £50 millions per annum.

What is to be our peace outlay upon armaments? In the year before the war the Army cost £28,300,000. It is my own belief that, notwithstanding the proposed League of Nations, the British Empire will find it very difficult for some years to come to reduce its standing Army below 500,000 men, and its annual expenditure on the Army below £80 millions.

In the year before the war the expenditure on the Navy amounted to £48,800,000. Naval shipbuilding costs 70 per cent. more than it did before the war. The development of the submarine may alter the whole conception of sea-power, and we shall get off lightly if we can keep our expenditure on the Navy below £70 millions per annum.

The third arm, viz., Aircraft, is yet only in its infancy, and an annual expenditure of £20 millions on this service would not be excessive.

Summarising the conclusions arrived at above, it may be estimated that our post-war expenditure will be as follows:—

	Millions. £
Civil Government Charge	150
Army	80
Navy	70
Aircraft	20
Interest and sinking fund charge on National Debt	325
Pensions, etc.	50
	695

Say, about £700 millions.

It would not be unreasonable to expect that the Empire should take over some share of the burden of Imperial defence. The money cost of defending the Empire has naturally fallen

mainly upon the United Kingdom. Our burden of war debt per head will be about £140, while that of the Overseas Dominions will probably be very much less.

We may apparently look forward to an annual expenditure of £700 millions. How is this vast sum to be provided? The Labour Party propose "a special capital levy to pay off a very substantial part of the National Debt, chargeable, like the death duties, on all property." This appears to me to be wholly impracticable in the form in which it is suggested by the Labour Party.

The advocates of a levy on capital do not seem to have any conception as to the form in which the "capital" of the country exists.

The following is a detailed estimate of the wealth of the United Kingdom which I laid before the Royal Statistical Society in 1914* :—

That would remove more than £700 millions from the valuation. Then the capital of the non-tax-paying classes is estimated to amount to £1,000 millions. The Labour Party obviously do not propose that there should be a 10 per cent. levy on the funds of the trades unions and co-operative societies, friendly societies, and the deposits in the savings banks. Again, movable property, that is, furniture, works of art, represents another £1,000 millions. How would the 10 per cent. levy be obtained from this form of property? The advocates of a levy say "there need be no fear about a flood of realisations; there will be no need of realisations, it will be largely a matter of book entries." Surely they do not propose that the Government should merely take over *inter alia* one-tenth of the furniture and works of art owned by the inhabitants of the United Kingdom.

	Income. £	Number of years' Purchase.	Capital. £
Under Schedule A—			
Lands	52,219,000	25	1,305,475,000
Houses	223,913,000	15	3,357,195,000
Other profits	1,297,000	25	32,425,000
Schedule B—			
Farmers' Profits	17,457,000	8	139,656,000
Schedule C—			
Public Funds, less Home Funds	35,049,000	20	700,980,000
Schedule D—			
Quarries, mines, ironworks	23,109,000	4	92,436,000
Gasworks, waterworks	19,588,000	20	391,760,000
Canals, docks, fishings, etc.	2,607,000	20	52,140,000
Other public companies	199,082,000	15	2,986,230,000
Foreign and Colonial Securities and Coupons	50,828,000	20	1,016,560,000
Railways in the United Kingdom	46,099,000	25	1,152,475,000
Railways out of United Kingdom	28,016,000	20	560,320,000
Other profits and interest	16,654,000	20	233,080,000
Trades and professions (one-fifth of total income of £222,676,000)	44,533,000	15	667,995,000
Total under income tax			12,688,727,000
Trades and professions omitted, 20 per cent. of amount assessed, or £44,533,000, of which one-fifth is	8,906,000	15	133,590,000
Income of non-tax-paying classes derived from capital	100,000,000	10	1,000,000,000
Income from investments abroad or from shipping, banking and mercantile services not brought home	60,000,000	15	900,000,000
Movable property not yielding income, *e.g.* furniture, works of art, etc.	—	—	1,000,000,000
Government and local property	—	—	750,000,000
			£16,472,317,000

It is clear that a large part of the above aggregate of £16,472 millions would not be available for assessment to a levy on capital. In the first place it may be pointed out that the capital of professional men, *e.g.* doctors, solicitors, accountants, underwriters, etc., consists mainly of their expert knowledge and business experience, and in their case there would be nothing to assess but the comparatively small investments owned by these men.

Another huge deduction must be made in respect of Imperial and local Government property, the value of which was estimated in 1912 at £750 millions, and it is now in the neighbourhood of £1,500 millions.

In 1913 Sir Bernard Mallet, President of the Royal Statistical Society, estimated the capital wealth of the country on the basis of property passing at death at less than £11,000 millions. When all the necessary deductions have been

* "Economic Relations of the British and German Empires," *Journal of the Royal Statistical Society*, June, 1914.

made, it does not appear that a larger sum than £10,000 millions would be available for assessment. Let us assume that sufficient pressure was brought to bear upon the Government to impel it to attempt to enforce an average levy of 10 per cent. on this amount, what would be the result? Securities, land commodities, etc., representing an aggregate value of £1,000 millions, might be transferred from private ownership to the ownership of the State. The bulk of these assets could not be sold. but they might bring in an income of £50 millions per annum; but as the Government would have been entitled to 25 per cent. income tax. in addition to super tax, it would, in any event, have received £12,500,000 of the income. Again, it would lose the benefit of the death duties on this mass of property, which might be estimated to produce about £3 millions per annum. The net result would, therefore, be an additional revenue of about £35 millions per annum, less the expenses of valuation and collection, which would certainly be very considerable.

The national revenue for 1913–14 was £198 millions, of which £163 millions were derived from taxation and £35 millions from non-tax revenue. From what sources are we to obtain a peace revenue of, say, £700 millions per annum?

What the Government wants is income, not capital. The capital of the Government consists of the country's power of production. For the year to March 31st, 1918, the Chancellor budgeted for a revenue of £638 millions, including £224 millions from income tax and super tax, and £200 millions from excess profits duty; the latter duty will probably bring in £230 millions and income tax £250 millions, and the total revenue for the year will probably show an increase of £88 millions on the Budget estimate, making the aggregate revenue £726 millions.

There are many alternative methods of meeting the charge for the national Government after the war, but it is of vital importance that we should adopt a course which will impose the minimum of hardship and will not check our industrial development. We must remember also the paramount importance of keeping our financial policy as far as possible in line with that adopted by the other great industrial countries, *e.g.* America and Germany. We have already gone much further than either of these countries in the matter of direct taxation, and it would be unfortunate if the treatment accorded to capital should be so much more unfavourable in this country as to divert both home and foreign capital from London.

We might continue the excess profits duty, but this is open to very grave objections: (1) that it constitutes a restraint upon the development of trade and tends to standardise production at the low level of 1913, and (2) that it will probably cease to yield any substantial amount of revenue in a few years after the war. Of course, this duty cannot be suddenly dropped, but I think it should be fixed for a period of, say, five years ahead on a descending scale, say 50 per cent. in the first year of peace, declining to 10 per cent. in the fifth year after peace. Another course would be to increase the income tax and super tax, but income tax is already at an oppressive level, and any further substantial advance would impose a check upon individual enterprise at a time when it should be most actively encouraged. The death duties will doubtless be further increased, and they might possibly be advanced considerably without causing undue damage to the economic system. There must be a further increase in the indirect taxation. The case for the adoption of such a policy is very strong. The working-classes are getting a larger share of the gross income of the country than they have had in the past, and they are not contributing their fair proportion of the cost of government. The wages bill has gone up by, at least, £500 millions since 1914, but indirect taxation has only advanced by about £30 millions. In 1913–14 indirect taxation was 43 per cent. of the total revenue; for 1917–18 it will amount to only 18 per cent. of the total revenue. It should be possible to obtain at least another £50 millions a year from indirect taxation.

As soon as peace has been declared the country will have to consider very seriously whether it can afford to continue the present preferential treatment accorded to farmers in respect of income tax. For the year 1913–14 farmers were assessed to Schedule B on the basis that their profits equalled one-third of the rent. The fact was, of course, that farms under 450 acres paid no income tax. A few farmers were assessed under Schedule D, but even those assessed under Schedule B had the right, if their profits fell below the statutory one-third, to get a special reduction to the actual profits of the year. The method of assessment for the current financial year is similar, save for the fact that the Schedule B assessment, instead of being one-third of the rent (plus tithe), is now the full rent.

It must be remembered that farmers are exempt from the excess profits duty, the reasons given for this being (*a*) the putting up of the basis, together with the lower exemption limits and abatements, put a larger burden of new income tax upon the industry than it had ever borne before; (*b*) for this duty some sort of accounts are essential, and farmers generally do not possess them, even if they were compelled to keep accounts for the future they would be lacking for the pre-war standard. The £200 exemption limit would cut out a large number from liability, and reduce the amount payable by the remainder. The excess profits duty generally, the bringing in of nearly two million taxpayers, and the immense complications of income tax, threw such an enormous burden upon the depleted staff that it could not take on this extraordinarily difficult and not very profitable task; (*c*) it may be added that the State aid being given to agriculture production is net and not gross—that is, that it would have to be revised if new burdens were thrown upon farmers.

The gross production of farmers before the war was valued at about £200 millions. For the current year I estimate it to amount to £400 millions. In 1913-14 farmers' profits were probably £50 millions, and they were only assessed at £17 millions. For the year 1917-18 I estimate farmers' profits at not less than £120 millions, but they will only be assessed at £52 millions; that is to say, instead of contributing £15-£20 millions of income tax and excess profits duty they will not pay more than about £5 millions. As a result of this exemption from excess profits duty, the practical exemption from income tax, and the special treatment which has been accorded to them in other directions, it may be safely affirmed that the capital of farmers has been practically doubled during the war. But even if effect were given to the proposals outlined above, it would not produce sufficient revenue for the purposes of the Government, and the best course which we can take appears to me to be the institution of a small annual tax on capital, graduated so as to yield an average return of 1 per cent. per annum on the capital wealth of the country, and to be strictly limited to a term of ten years. An exemption limit of, say, £2,000 might be adopted. If such a tax were imposed it should yield a revenue of not less than £120 millions per annum in the United Kingdom. The method of assessment should be comparatively simple and inexpensive. Each taxpayer, when making his return to income tax, should be required to include a valuation of his capital. In case of dispute the valuation should bear a certain specified ratio to the gross income assessed to income tax, the ratios varying in relation to the nature and state of development of the property. The income tax returns would provide an annual check, but if there should be found to have been evasion the arrears could be recovered when the estate ultimately came to valuation for probate purposes. If effect were given to the above proposals, the post-war revenue might be as follows (the actual revenue for 1913-14 and the estimated revenue for 1917-18 are included for comparison):—

	Actual Revenue for 1913-14. Millions. £	Estimated Revenue for 1917-18. Millions. £	Estimated Post-War Revenue. Millions. £
Customs and Excise .	75	105	150
Estate Duties . . .	27	29	50
Stamps, Land Tax, etc.	14	10	15
Income Tax, say . .	47	250	250
Non-tax Revenue . .	35	69	70
War Tax on Capital .	—	—	120
Excess Profits Duty .	—	230	50*
Miscellaneous . . .	—	33	—
	£198	£726	£705

* Average for, say, 10 years.

It should, therefore, be possible, by increasing indirect taxation to £150 millions, by advancing the death duties and by instituting a small annual tax on capital, to meet our post-war charges, to abolish the excess profits duty in five years after peace, and to maintain the income tax at the present standard rate of 5s. in the £. In 1929 the Government will have the option of paying off the 5 per cent. War Loan, and many of the other Government obligations will become liable to redemption. It is probable that we shall then be in a position to reduce the rate of interest and consolidate the war debt, and if the monetary conditions are suitable we might issue a Consolidation Loan at the rate of $3\frac{1}{2}$ per cent. Of course, due consideration must be given to the condition of the money markets, the cost of living, and the rate of the income tax. A reduction of $1\frac{1}{2}$ per cent. interest on £6,000 millions would mean an annual saving of £90 millions per annum to the Exchequer. I think, therefore, that for the next decade we should adopt what I would term a transition stage in national finance, and at the end of that time reconsider our national economic policy.

Expenditure must always be considered in

relation to income, and we must remember that in 1914, when the Imperial expenditure was £200 millions per annum, the national income was about £2,400 millions per annum. That is to say, the cost of Government represented about 8 per cent. of the entire national income. What is the national income at the present time? In order to show this I have prepared the following estimate of the income and expenditure of the United Kingdom for the years 1907 and 1917 respectively:—

(in 000,000 £)

	1907.		1917.	
Food, etc.	483·1		875	
Dress	248·0		320	
House	246·0		260	
Miscellaneous	186·3		150	
Cost of distribution	200·0		300	
Professional and Domestic Services	100·0		60	
	1463·4			1,965
National Service, including Army and Navy, Local Government	184·0	War and other Expenses of Government incurred at home	1,800	
	1,647·4			
Depreciation, repairs, renewals, etc.	180·0	*Less* cost of feeding, clothing, and maintaining 6,000,000 soldiers and sailors, 2,000,000 munition workers and their dependents, allowed for above	300	1,500
New Investment at home	150·0			
Capital invested abroad	176·0			
	£2,153·4			£3,465

From the estimates furnished in the above table, it may be said that while in 1907 we produced commodities and services sufficient to feed, clothe, and maintain us, and leave a surplus of £506 millions for repairs and renewals and new investments at home and abroad, in 1917 we produced commodities and services sufficient to feed, clothe, and maintain us, and provide a surplus of £1,500 millions, which we devoted to the carrying on of the war, but there was practically nothing available in 1917 for renewals and new investments. This great surplus was produced partly by increased production, partly by restricting consumption, partly by using up accumulated stocks, and partly by the rise in prices. It will be noted that I estimate that the national income advanced from £2,153 millions in 1907 to about £3,500 millions in 1917. This estimate is borne out by the amount of gross income brought under the review of the Commissioners of Inland Revenue, which advanced from £980,117,000 in 1907–08 to £1,600,000,000 in 1916–17. The number of income tax payers in 1913–14 was 1,200,000 and in 1916–17, 3,200,000.

The solution of our domestic post-war financial problem can only be found by increased production. If we can maintain the production of the United Kingdom at not less than £3,600 millions per annum, the estimated Imperial expenditure of £700 millions per annum will not amount to more than 20 per cent. of the national income, and this is a burden of taxation which the nation should be able to bear with comparative ease.

I believe we can maintain the production of the United Kingdom at the level I have indicated if we profit fully by the lessons which the war has taught us as to our faulty ideas of commercial organisation and the unhappy relations that existed between capital and labour before the war. We were then only producing from two-thirds to one-half of the commodities and services we were capable of producing.

An interesting statement with regard to pre-war industrial conditions and output was made in a report of the Mechanical Section Committee of the Iron and Steel Institute issued in the latter part of 1917 as to the causes of the smaller output of steel in British steelworks as compared with foreign practice. On the question of labour conditions the report states: "there is a general agreement that our labour conditions, as compared with the Continent, are detrimental to output. It is not, however, suggested that this is due to inferiority of the men individually . . ."

The following is a comparison of melters' earnings in several countries before the war:—

EARNINGS PER SHIFT (PRE-WAR FIGURES).

	English.		American.		German.	
	s.	*d.*	*s.*	*d.*	*s.*	*d.*
1st hand	36	11	17	4	9	6
2nd "	24	9	11	3	7	0
3rd "	18	3	9	9	5	6
Total	80	1	38	4	22	0

The weight of steel made per shift is approximately in the ratio of :—

English.	American.	German.
1·0	1·5	2·0

The report continued: "We look upon the question of labour as a most important one. The wages are so high that it is useless to expect men to make extra exertion to gain more. It seems, therefore, that in order to increase the output it is necessary to reduce the effort required from the workman by every possible means, and this can only be done by a well-laid-out and well-organised plant."

The accuracy of the above figures was challenged, but the general conclusions of the Committee appear to have been fully established.

A report by another Committee of the Iron and Steel Institute as to the causes of the smaller output of steel in British steelworks as compared with foreign practice stated that "Military training on the Continent makes the men there more obedient and methodical in their ways than in England . . ."

The opinion is expressed that if the steel trade of Britain is to hold its own in open competition with the other steel-producing countries of the world, it will be necessary, amongst other changes, to have a Control Board to which all orders will go and from whence the work will be allocated to the different works according to their ability to do it.

"It is clear to the Committee that the one outstanding feature which has been revealed by their work, so far as it has gone, has been the eliciting of the almost unanimous opinion that, if the steel industry of this country is going to maintain its position, it must be by some great broadening of our commercial organisations that would lead to economies far and away outweighing any other element in the situation, and long ago realised and adopted by our foreign competitors."

In my second lecture I have given my reasons for the belief that during the war the power of production of the United Kingdom has increased by 30 to 40 per cent., and I believe that, from the point of view of industrial expansion, the war has advanced us by two generations. The Coal Conservation Subcommittee of the Committee of Reconstruction in their Interim Report (Cd. 8880) give a most encouraging view of the prospects of increased production after the war.

The following is a summary of the conclusions of the Committee* :—

1. The coal consumption involved in the production of motive power in the United Kingdom amounts at the present time to 80,000,000 tons per annum, equivalent in value to, say, £40,000,000 at pit head.

2. In the industrial reorganisation which must take place on the termination of the war the further development of power is of great importance. The present use of motive power per employer is only about half that in the United States. Large quantities of electrical power will be required for the development and carrying on of new processes not at present undertaken in this country. Processes involving some millions of horse-power at present worked in America, Norway and Sweden, Germany, etc., can be profitably carried on, and having in view the desirability of making all essential products in the Empire, should be carried on in this country.

3. It is only by largely increasing the amount of power used in industry (by two or more times) that the average output per head (and, as a consequence, the wages of the individual) can be increased. The pre-war earning power, or wages, of each individual was far too low.

4. Power may be most efficiently applied to industry by the medium of electricity.

6. Technically and economically the electrical energy can best be provided by a comprehensive system which will provide for power production in large super-plants.

9. If power supply in the United Kingdom were dealt with on comprehensive lines and advantage taken of the most modern engineering development, the saving in coal throughout the country would, in the near future, amount to 55,000,000 tons per annum on the present output of manufactured goods.

10. If the coal so saved were used for the production of further power it would be possible to generate continuously not less than 15,000,000 horse-power, which would more than compensate for the absence of large water-powers in this country, and admit of the manufacture here of many products which are at present only made in America and on the Continent.

The average coal consumption per horse-power throughout the country has been halved during the last twenty-five years . . . the present coal consumption would, if used economically, produce at least three times the present amount of power.

Assuming that we can reconstruct the national finances on the lines I have indicated and at the same time increase our production over the pre-war level by about 50 per cent., what is the economic problem which we shall have to face after the declaration of peace? We shall have to provide work for four or five million men who are at present in the Army and Navy or employed as munition workers, and one million

* Reconstruction Committee, Coal Conservation Subcommittee Interim Report on Electric Power Supply in Great Britain. (Cd. 8880.)

women who are employed in munition works. At the same time we shall have to readjust our foreign trade policy to the new position which we shall hold in international finance.

A sub-committee of the executive of the Labour Party have put forward an interesting programme of reconstruction. The report states, *inter alia*, that, in order "to prepare for the possibility of any unemployment either during demobilisation or in the first years of peace, the Government should make preparations for putting instantly in hand . . . such urgently-needed public works as :—

(*a*) The rehousing of the population to the extent possibly of a million new cottages and an outlay of £300 millions sterling.

(*b*) The immediate making good of the shortage of schools, training colleges, technical colleges, etc., and the engagement of the necessary staffs.

(*c*) New roads.

(*d*) Light railways.

(*e*) The unification and reorganisation of the railway and canal system.

(*f*) Afforestation.

(*g*) The reclamation of land.

(*h*) The development and better equipment of our ports and harbours.

(*i*) The opening up of access to land by co-operative small holdings and in other practicable ways.

It is extremely disappointing to find that an important body who will have such a large share in the determination of the future economic policy of this country should have taken such purely domestic views of our post-war problems. We cannot afford such an extravagant programme of internal development until we have restored our position in foreign trade.

The report states: "To-day no man dares to say that anything is impracticable." I will dare to say that it is impossible to evolve a satisfactory and adequate scheme of economic reconstruction unless it is based upon (1) a great increase in the production of commodities and services in the United Kingdom, and (2) a vast expansion of our foreign trade. We all recognise that domestic reforms are urgently necessary, that our agricultural industry must be fostered, and that home industries, particularly the dye and chemical industries, must be greatly developed, but whatever paper schemes we may adopt we shall ultimately find that they are of little account unless they comply with the two conditions which I have laid down above. The extent to which we can expand our foreign trade is, therefore, a matter of profound importance.

The Government are at present spending in this country about £5 millions per day. During demobilisation they will not probably spend much more than £2 millions per day. Who is going to take the place of the Government as the purchaser of commodities or services to the value of £3 millions per day?

It will be a much more difficult task to move from war production to peace production than it was to move from peace production to war production. In the latter case we had at our disposal the wealth and resources accumulated through a century of industrial expansion. The manufacturer, in transforming his works, knew that he had behind him a Government contract at, to say the least of it, remunerative prices with no risk of bad debts or a falling off in the demand. How is the British manufacturer to shape his peace programme and to move from war production to peace production with a heavy burden of taxation and a problematical demand for his production and an unknown volume of competition from foreign manufacturers?

Before the war we imported mainly foodstuffs and raw materials and exported manufactured goods and coal, and it does not seem probable that the war will make any fundamental alterations in our dependence upon foreign trade. We shall make some progress in the matter of growing a larger supply of food at home, but it is quite out of the question for us to grow all the food we require at home. With regard to raw materials, we shall be still more dependent upon foreign supplies than we were in 1914.

By the command we had of the markets of the world, and the economic momentum which was given to our trade by the interest on our investments abroad and the earnings of our shipping, insurance companies, etc., we could determine in a large measure the nature of our imports. It is of vital importance that we should arrive at a clear understanding of our international position as it will appear after the war, and know whether we shall have this command of the markets of the world. Shall we still be a creditor nation? Shall we still have capital available for investment abroad on a large scale?

Before the war we entered upon each year of foreign trade with the comfortable knowledge that we should have at the end of it

a credit of about £400 millions made up as follows:—

	Millions.
Interest on Investments	£200
Earnings from Shipping	100
Earnings from Banking, Insurance, etc.	100
Total	£400

We therefore began the war the greatest creditor nation in the world because we carried, financed and insured more than one-half of the world's sea-borne commerce and the world was indebted to us for £200 millions a year by way of interest on investments. Our pre-war foreign investments have shrunk from £4,000 millions to £3,000 millions, but on the other hand we have made new investments abroad during the war to the extent of £1,500 millions. Before the war the foreign holding of our National Debt was negligible. It now probably amounts to £1,000 millions. If these conclusions are approximately correct we stand to receive only £225 millions as interest on investments, that is assuming our loans to our Allies and the Dominions are good (an assumption which is by no means justified at the moment). On the other hand we shall have to pay £50 millions per annum by way of interest on British Government securities held abroad. On balance, therefore, we should stand to receive £175 millions by way of interest on investments.

With regard to food imports, for the five years preceding the war our purchases, including drink and tobacco, averaged £270 millions per annum. We shall probably grow a larger proportion of foodstuffs at home, but even if we should be able to provide supplies for five days in each week, which I very greatly doubt, the cost of food for the two days will, owing to the increase in prices, probably amount to as much as the pre-war imports for three and a half days per week.

What are our earnings from shipping, banking, etc., services likely to amount to? Our mercantile marine has shrunk from over 20 million tons gross to between 16 and 17 million tons gross, but owing to the high freights that must obtain for some years after the war it seems not unreasonable to assume that our earnings from shipping will be in the neighbourhood of £200 millions per annum. Until the international financial system has been re-established it would not be reasonable to expect that our earnings from our share in the financing of international trade will approach the pre-war standard; but, on the other hand, earnings from insurance, underwriting, etc., will probably be increased, and the two items of banking, insurance, etc., should produce not less than £60 millions per annum.

We should, therefore, be able to count upon a credit balance of about £400 millions per annum, made up as follows:—

	Millions.
Interest on Investments held abroad	£225
Less Interest on British Government Stocks held abroad	50
	£175
Earnings from Shipping, etc.	200
Earnings from Banking, Insurance, etc.	60
	£435
Deduct from this, say, 5 per cent. on £700 millions of loans to Allies which may not bear interest for some years after the war	35
	£400

On the basis of these calculations we should, therefore, be nominally as well off as we were before 1915; but on the new basis of prices a credit of £400 millions after the war will not be worth anything like a credit of £400 millions before the war, and to this extent we shall be in a less favourable position in relation to international trade.

All the conditions essential to a vast development of international trade should be in existence after the war. The principal trading countries of the world have depleted their stocks of manufactured goods and raw materials, and all neutral countries which produce foodstuffs and raw materials have, under the stimulus of economic pressure, extended their power of production of these commodities. In our own case we have increased the power equipment of our industries. We have introduced labour-saving appliances and revolutionised our industrial methods. We shall have a larger industrial population, including women, than we had before the war, and when demobilisation has been in operation for a year or so our production—that is to say, our wealth-producing power—should be at least 50 per cent. greater than it was before the war.

One of the most difficult questions in connection with the expansion of our foreign trade will be the problem of the foreign exchanges, some of which are now heavily against us. We do not know with any accuracy the extent of foreign holdings of our Treasury Bills, Exchequer Bonds and Currency Notes, etc., but we do know that the aggregate amount must be very considerable. In November last Mr.

Bonar Law told us that we were then indebted to the United States to the extent of nearly £400 millions. We have paid large sums to Holland for Java sugar and large amounts to Japan for ships and munitions. We have paid large sums to South America for foodstuffs and raw material, and it is common knowledge in the City that the great American financial institutions are employing very large sums in the London Money Market. With regard to Egypt, the *Times* of November 28th, 1917, stated: "There is ample evidence that practically the entire surplus income of the country (*i.e.* Egypt) since the outbreak of war, computed at about £40 millions, had been invested in War Stock, principally British." The building up of our gold reserve is, therefore, a matter of the first importance.

Altogether, I estimate that from the beginning of the war down to the end of 1917 we borrowed abroad, or obtained credits abroad through the sale of investments amounting in the aggregate to—

Millions.	
£350	in 1915
600	in 1916
900	in 1917
£1,850	

Of this total about £850 millions represent British holdings of foreign securities, principally American, which we have sold back to America, Japan, etc., leaving us with a net indebtedness of, say, £1,000 millions. Against this we may place the remainder of our pre-war foreign investments, say . . . . £3,000 millions

Add Investments made abroad during the war (that is loans to the Allies and Dominions), say	1,500	,,
	4,500	,,
Less moneys owing to the United States, etc.	1,000	,,
Balance	3,500	,,

The conditions under which our foreign trade will be carried on during the years immediately following peace, cannot possibly be the same as before the war. We shall probably have to pass through a transition stage which may extend over a decade. During the five years preceding the war we used to invest about £200 millions per annum by way of loans to Colonies and foreign countries. On the present basis of prices this average would represent a value of £400 millions per annum, but if we intend to make good our war losses as quickly as possible and provide employment for the men who are coming back and the munition workers who will be discharged, we must make provision for the investment of much larger sums abroad in the transition period. I think it should be not less than £600 or £700 millions per annum. This is quite feasible. In its ultimate form it represents the excess of production of commodities and services over the consumption of commodities and services. It should be quite practicable for this country, while relaxing the war strain on the industrial population, to produce £800 or £900 millions more services and commodities than it consumes, provided the co-operation of capital and labour is obtained.

The weakest point in our position is that of shipping. We have lost about four million tons, and the remainder of the tonnage is in need of repair and overhauling, but the new shipbuilding programmes in this country and America should improve the position.

It is a national misfortune that the nation should have been manœuvred into an attitude of hostility to the shipowners. Thanks to private enterprise, we possessed at the outbreak of war a vital and incomparable weapon without which the nation could not have carried on the war. The course of freights since the Government requisitioned shipping has proved conclusively that the shipowners, in allowing the law of supply and demand to take its course in fixing rates, were acting on sound and, in the circumstances, inevitable lines, and that the charge of profiteering was due to the economic ignorance and the jealousy of sections of the British public. The recovery of this country from the economic wastage of war will be gravely menaced if the State attempts to continue a day longer than is absolutely necessary the control of shipping, and I would suggest that our shipowners should take the Labour leaders into their confidence and discuss this vital question, for on a clear understanding of the issue the future of the British Empire must largely depend.

We shall have to grant loans to foreign countries and the Dominions on a vastly greater scale than ever before, and this we can most easily do by the creation of joint-stock companies.

The whole ground should be comprehensively surveyed. We must see what tonnage we are likely to have, what supplies of raw materials will be available, what our principal foreign customers require, what we can manufacture, and what they can sell us in exchange, and

then form overseas development corporations for Canada, Australia, India, South Africa, New Zealand, West Africa, Egypt, Mesopotamia, Palestine, East Africa, and the Crown Colonies. We must also provide for the development of trade with Belgium, France, Italy, Serbia. It will not be an easy matter to hold the balance between the claims of our different Allies for the expansion of our trade, but it is obvious that the development of Empire trade must be our first consideration.

During the war we have evolved the machinery requisite for the transference of a great portion of the resources of the country to the State, *i.e.* through War Loans. In the transition period we must provide machinery for the retransfer of these resources from the State back to the individuals—that is, from War Loans into oversea joint-stock enterprises. The banks must either provide loan facilities on a vast scale or establish a great national loan institution, which will accept War Loans, National Bonds, etc., as collateral, and issue in exchange therefor credit notes, which could be applied for the purpose of subscribing capital for these overseas enterprises in such a manner as will prevent inflation of credit. Unless some such machinery is provided, there is a danger that the market will be flooded with sales of war stock, etc., by holders who wish to take up again their industrial and commercial occupations, and require cash for the purchase of manufactured goods or raw materials.

Any attempt to exploit the Crown Colonies or the overseas Dominions, or foreign customers, for the purpose of liquidating our war debt will prove impracticable, and will lead to disaster. The whole scheme must be conducted on a strictly business basis; but, above all, the machinery for the expansion of our foreign trade must be kept as far as possible out of the control of the bureaucrats.

Concurrently with this vast expansion of our foreign trade we must be prepared with an equally big scheme of Empire settlement. Before the war emigration was proceeding from the United Kingdom at the rate of 300,000 per annum. It may be confidently assumed that this rate will be accelerated after the war. There can be no question as to the need for this if the Empire is to maintain its position in the world. An interesting comparison between the British and Roman Empires is made in the final report of the Dominions Commission. It states: "The Roman Empire, being concentrated and continuous, escaped some of the difficulties which confront the British Empire. The extreme distance between the capital and its furthest dependence was at the most 2,000 miles, whereas the extreme distance between London and the outer borders of the farthest self-governing Dominion is over 12,000 miles, or half the circumference of the earth. In a sense, such spaces have been annihilated by the use of electricity, and their inconvenience mitigated by that of steam. Still, as the present war teaches, routes so extended must always remain open to attack, and add to the anxieties of Government.

"Where figures are concerned certain salient facts emerge from the shadows of the past. The approximate size of the Roman Empire was 1,400,000 square miles. Canada, with nearly 4,000,000 square miles, and Australia, with 3,000,000 square miles, are each more than double this size. If to those areas be added that of the British Isles, with the three smallest of the self-governing Dominions—namely, New Zealand, the Union of South Africa, and Newfoundland, about 750,000 square miles in all—it will be seen that those portions of your Majesty's Empire alone overpass the area of that of Rome in a ratio of five to one.

"Again, an approximate estimate of the population of the Roman world in the time of its greatest prosperity was 85,000,000. In all the regions conquered by Rome there were indigenous populations of varying density.

"In the self-governing portions of your Majesty's Empire we find that their 65,000,000 inhabitants (including more than 5,000,000 natives in the Union of South Africa) are most unequally distributed. Of these no less than 45,000,000 live in the small islands which form the United Kingdom, leaving but 20,000,000, inclusive of all populations of non-European blood, to occupy the more than 7,000,000 square miles of the five oversea Dominions. It is, however, in the scale on which the population migrated from the homeland to the outlying parts that there lies the most striking contrast between the ancient Empire and those parts of your Majesty's possessions to which our inquiries have extended.

"Rome was not a colonising power in our sense of the word, but one whose chief object was to rule and hold. In her case the occupation and development of the distant parts of the Empire was not the lifework of hundreds of thousands of the best of her citizens. Her settlements were confined to the establishment of small groups, largely composed of disbanded

legionaries, in selected centres on frontiers, military highways, and trade routes.

"British rule is directed to ends widely different in character. Its policy is not merely directed to secure settlement in chosen spots, but to encourage it in all the wide areas within the Empire's boundaries, suited for the maintenance and well-being of its people. All that is asked of those who find a new home overseas is to assist in the development of the country of their choice in whatever manner best suits their training and inclination."

We could not have built up and held the British Empire if we had not encouraged our people to emigrate, and it cannot be doubted that the United Kingdom has attained a much more powerful position in the world and a greater efficiency in war from the emigration of her sons and daughters than she would have attained if she had restricted their emigration.

A general process of consolidation and reorganisation is going on throughout the country, both with regard to capital and labour. The great joint-stock banks are amalgamating. The shipping companies and great industrial undertakings, such as coal, iron, and steel, are amalgamating. Employers are consolidating their forces into a smaller number of federations, while the Labour Party has been reorganised, and the women are developing their organisations. Our Consular system has been reorganised and an Overseas Intelligence Department elaborated. But all these measures will bear little fruit unless there is co-operation between capital and labour, which will result in a great increase of production.

There is a widespread disposition to underrate the achievements of this country in the matter of organisation for war. We began the war with an Expeditionary Force of 160,000 men. We have now over 3,000,000 men serving overseas. We have in Mesopotamia one of the largest armies that has ever been assembled east of Suez. We have got large armies in Egypt, Palestine, and Salonika. In addition to maintaining and feeding our own troops, we are supplying war materials, food, etc., on a scale sufficient to maintain 3,000,000 fighting men of our Allies. Our economic position is perfectly sound. We have entirely revolutionised the character of our national production, and we are now producing commodities and services nearly equivalent in value to the commodities and services requisite to maintain our population at home and to carry on the war, and I see no reason to doubt that Great Britain can continue to carry this stupendous burden if the people do not weaken in their resolve, and provided we maintain our mercantile marine.

GENERAL NOTES.

Comparative Uses of Wood, Steel, and Concrete Poles.—Mr. F. L. Haushalter, writing in the *Electrical Review*, Chicago, discusses the costs of poles for use on telegraph, telephone, or low-voltage power lines under urban or inter-urban conditions. He considers that treated wood is best for these purposes, partly because the tree had been naturally adapted to resist stresses precisely similar to those to which the pole is exposed. Concrete poles compare favourably with steel poles at the prices worked out by the author, but something depends on local conditions and needs. Little is known as yet as to the life of concrete poles, though it has been found that moisture, absorption, and repeated drying-out affect certain grades of concrete. The life of steel embedded in concrete is thought to be practically indefinite. The greatest disadvantage in connection with concrete poles is the fact that they are of great weight, and cannot be so readily transported as steel poles; they are therefore usually made on the ground where they are to be used. There is also the difficulty of obtaining good sand and water.

British Manufacturers and Oversea Markets.—The most frequent charge levelled at British manufacturers, says the *Board of Trade Journal*, is that they are—or were—unwilling to make goods in accordance with the requirements of a particular market. It is probable that this charge had less evidence to support it than has been generally supposed. It assumes for its truth the existence of a system of standardisation among British manufacturers generally which is not apparent to investigators. How, then, did the belief become almost universal that British manufacturers are less adaptable to overseas conditions than their German rivals? The reply is, first, that many British manufacturers have in the past neglected to study the overseas markets with the meticulous care devoted to them by the Germans: and, secondly, that the oversea buyers have not explored with sufficient patience the field of British production. In the new world upon which we shall enter after the war is over, British firms will still have to contend against and break down a deep-rooted conviction abroad that they are rigidly conservative. In the meantime they can emphasise their readiness, whenever it is practicable, to make the goods which their customers want to buy.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

NOTICE.

EXAMINATIONS.

The results of the Elementary Examinations (Stage I.), held from May 6th to the 15th, were sent to the centres concerned on the 19th inst. The results of all three stages of both the March and May examinations have now been issued.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

HIGH TEMPERATURE PROCESSES AND PRODUCTS.

By Charles R. Darling, A.R.C.Sc.I., F.I.C.

Lecture I.—Delivered January 21st, 1918.

In comparing workshop processes at present in use with those employed twenty years ago, many striking changes may be noted, all tending to cheaper and more rapid production. It will be found, on examination, that some of the most important of these changes are due to the utilisation of high temperature processes, or to appliances in which new materials, produced at high temperatures, are employed. The surfacing of metals, the boring of metal cylinders, the cutting of granite, marble, and other stones, and many other operations which involved the use of steel tools, are now frequently carried out by grinding, the abrasive material being usually an electric furnace product. In another direction, the use of the oxy-acetylene flame for cutting iron plates, and for welding, has proved of immense importance, and is now quite indispensable; and here again the material which has rendered the extensive use of acetylene possible—calcium carbide—is made in the electric furnace. A further important development has been the introduction of "thermit" processes, in which aluminium is used as a reducing agent with the production of an extremely high temperature; and here also the electric furnace is involved as an essential to the production of aluminium. At the present time, when the economic generation of electricity in this country by the aid of large, central power-stations is under consideration, the present and future importance of high temperature processes and products cannot be too strongly emphasised. In any scheme that may be evolved, provision should be made for electric furnace work on the large scale, as otherwise we shall remain, as heretofore, dependent upon other countries for most of the materials dealt with in the present lectures.

For our immediate purposes, a high temperature process will be considered as one that cannot be conducted by the combustion of ordinary carbonaceous fuel in air, and which therefore demands the production of a temperature above 1700° C. This degree of heat may be exceeded by special methods of combustion, or, better still, by the aid of electricity. In chemical actions the energy set free appears in the form of heat, and produces a temperature which, in any given case, cannot exceed a certain maximum; and no instance is known in which a temperature higher than 3000° C. is obtained by chemical means. In the case of electrically produced heat, a conversion of energy takes place without chemical action, and the temperature procurable is only restricted by the dissipation of the material in which the heat is generated, so that in practice 3700° C. can readily be produced.

Chemical actions are profoundly influenced by temperature. In almost every case combination is impossible at very low temperatures, such as that of liquid air (−184° C.); and on the other hand, at temperatures of the nature of 6000° C.—approximately that of the sun—compounds cannot exist. It follows that in every case there is a definite temperature at which combination will commence, and a certain higher temperature at which the compound produced will decompose. Mercury, for example, when heated nearly to its boiling-point, combines with oxygen to form mercuric oxide, and liberating heat according to the following equation:—

$$Hg + O = HgO + 207K \text{ (kilo-calories)}.$$

When, however, the oxide is heated to about 500° C., the equation is reversed, mercury and oxygen being set free, and 207K absorbed from the source of heat. It is evident that in all

cases the temperature produced by a chemical action cannot exceed that at which the decomposition of the product commences, and it is this factor that chiefly determines the temperature actually obtained in any given case. Calculations are sometimes made with a view to finding the temperature of a reaction from thermo-chemical data; but owing to the restriction stated above the results are frequently very far from the truth. As an example, 2 grams of hydrogen combine with 16 grams of oxygen to form 18 grams of steam, 68·4K or 68,400 gram calories of heat being liberated. If all this heat were applied to the steam produced, the resulting temperature should be $\frac{68,400}{18 \times \cdot 5} = 7600^\circ$ C., the specific heat of steam being approximately 0·5. In practice, however, the temperature obtained by burning hydrogen in oxygen is about 2500° C., or only about one-third of the calculated value, owing to the attainment of the limit at which the reaction would reverse.

When a combustible material is burnt in air the temperature is lower than when pure oxygen is used, owing to a large part of the heat being carried away by the nitrogen, which forms four-fifths of the air, and takes no part in the chemical reaction. Increasing the rate of combustion by means of a blast produces a higher temperature with all kinds of fuel; but in no case is the degree of heat attained comparable with that procured by the use of pure oxygen. The combustion of coal gas in air, with a view to obtaining high temperatures, has received considerable attention during recent years. High pressures result in higher temperatures, and in this connexion Sir Robert Hadfield has recently called attention to some early experiments of Bessemer, in which pressures of the nature of 100 atmospheres were employed, and has suggested that further research on these lines is desirable. It is worthy of note that the temperature obtained on firing the compressed charge in a gas engine is about 2000° C. In another direction, Professor Bone * has shown that when coal gas and air are caused to burn without flame in the pores of a solid, a temperature approaching 2000° C. may be obtained. By altering the ratio of gas to air, and making provision against "firing back," Méker has produced a burner which gives a much higher temperature than an ordinary Bunsen flame, exceeding the melting-point of platinum (1753° C.). At present, however, no means have been discovered of burning a mixture of coal gas and air so as to produce the temperatures requisite to conduct the processes dealt with in the present lectures. The regenerative system of heating, introduced by Sir William Siemens, and now in general use in steel-smelting furnaces, is capable, theoretically, of producing temperatures of 2500° C. or more; but in practice is restricted to the point at which the refractory material used as lining for the furnace, and for the pre-heating chambers, undergoes destruction, the limit with silica bricks being below 1800° C. Even if a refractory capable of withstanding 2500° C. could be procured in sufficient quantity, it is doubtful whether this process could to any extent supersede the electric furnace for operations at very high temperatures. Greater possibilities in this direction would be opened out if oxygen could be produced so cheaply as to permit of its use in large furnaces; but under existing conditions fuel combustion cannot compete with electricity in the highest regions of temperature. The fact that oxygen is a waste product in certain processes for fixing atmospheric nitrogen may, however, lead to important developments in fuel furnaces. It may be pointed out here that, in general, a higher temperature may be obtained in the interior of a furnace than in the open, as in the former case the heat losses are due only to conduction through the furnace walls, whilst in the latter a far greater loss occurs owing to convection and free radiation. As the heat radiated from a hot substance increases as the fourth power of its absolute temperature, it follows that the production of high temperatures in the open is opposed by radiation in a rapidly increasing degree as the temperature rises. The specific radiating power of flames containing no solid matter, such as the oxy-hydrogen, is very small; but is high in the case of a solid fuel burning in air or oxygen, and the temperature attainable in the open is thus seriously reduced.

With this brief statement of the conditions affecting the production of high temperatures, we may now proceed to enumerate the successful methods which are of practical utility, and to indicate the uses of each. These are summarised in the table on page 623.

The temperatures given can only be regarded as approximate, as determinations by different observers vary by 100° or more, according to the type of pyrometer used. It will be seen, however, that all greatly exceed the temperatures attained in ordinary furnaces. The various methods and their uses will now be considered.

* Howard Lectures on "Surface Combustion," 1914.

Process.	Approximate temperature (Degrees C.).	Practical uses.
Oxy-hydrogen flame	2,500	Smelting of metals; welding; metal-spraying; working of vitreous silica.
Oxy-acetylene flame	3,000	Cutting of metal plates; welding.
Electric arc	3,700	Welding; production of nitrates from atmospheric nitrogen.
Thermit	2,500–3,000	Welding; production of carbon-free metals and alloys.
Electric furnace	3,700	Smelting of various metals; production of compounds such as calcium carbide, carborundum, graphite, etc.; manufacture of alundum, and vitreous silica.

in the order in which they appear in the table given.

The Oxy-hydrogen Flame.

The intense degree of heat produced when a jet of hydrogen is burnt in oxygen was first observed by Dr. Robert Hare, of Philadelphia, who invented the oxy-hydrogen blowpipe in 1801. In a description of his experiments, published in the following year, Hare stated that he was "enabled to fuse several of the pure earths which had previously been deemed infusible, and likewise, not only to fuse, but to volatilise pure platinum." At a later date, by multiplying the jets and using high pressure, Hare succeeded in fusing more than two pounds troy of platinum into a malleable mass.

One of the chief uses of the oxy-hydrogen flame since its inception has been to smelt platinum and allied metals, and to produce alloys of these metals. Deville introduced a furnace made of lime, into which the flame was directed through a hole in the top, and this form of furnace is still in existence for smelting platinum. Amongst the useful alloys prepared by this process may be mentioned those of platinum and iridium, used for fuze-wires in detonators for military purposes, and also for thermo-electric pyrometers; and platinum-rhodium alloys, also used in pyrometers. Iridium, owing to its hardness, is used for the tips of fountain pens. The advantage of the oxy-hydrogen flame in this connexion is that no impurities are introduced, as might be the case if electric smelting were substituted. Small welding operations on articles constructed of platinum are also carried out by means of the oxy-hydrogen flame.

The welding of iron can also be accomplished by this source of heat, and equipments for this purpose have been used in the repair of boilers, etc., as an alternative to patching and riveting. The oxy-acetylene flame, being hotter, is now more generally used for this and similar purposes, as will be described later.

One of the most recent applications of the oxy-hydrogen flame is to the spraying of metals on to cold surfaces. In what is known as the Schoop process the metal, in the form of wire, is fed into the interior of the flame, where it is melted and then blown by compressed air, in a state of very fine division, on to the surface to be coated. The arrangement is such that when the size of the flame is increased or decreased, the feed of wire is changed simultaneously, so that the rate of deposit per unit area is constant. The finely-divided metal fills all the interstices of the surface upon which it impinges, and becomes firmly attached; and by continuing the process any desired thickness may be deposited. By this method surfaces may be coated with metals of high melting-points, such as nickel, and the working costs are low. The figures appended indicate the consumption of materials involved in the case of several metals (see table on page 624). As might be expected, the metals of higher melting-points require more hydrogen and oxygen, and, owing to their less fluid condition, a stronger blast of compressed air to atomise and project on to the surface.

It is found in practice that a coating of metal may thus be formed on wood, plaster, glass, pottery, and even on fabrics, as well as upon the surface of other metals. Thus a wooden object may be strengthened by a coating of brass; medallions obtained by spraying on to plaster, which is afterwards removed; seamless metal tubes may be made by spraying on to a detachable former; and wooden tanks may be lined *in situ* with copper or other metal. Structural steelwork may be protected from corrosion by coating with zinc or aluminium, and many other applications could easily be found. It is

One Square Foot of Surface Sprayed to a Thickness of One-Thousandth of an Inch.

Metal.	Weight sprayed.	Time.	Hydrogen used.	Oxygen used.	Compressed air used.	Cost, not including cost of metal.
	Grams.	Minutes.	Cubic feet.	Cubic feet.	Cubic feet.	*d.*
Copper	20	1·5	3·5	1·2	60	0·7
Zinc	17	0·4	0·5	0·17	15·5	0·25
Aluminium	6	0·6	0·6	0·2	22·5	0·3
Lead	26·5	0·1	0·2	0·07	4·3	0·08
Tin	18	0·25	0·35	0·12	9·0	0·08
Brass	17	1·0	1·6	0·55	40	0·5
Nickel	10	2 0	4·2	1·4	80	1·5

interesting to note that aluminium, which cannot be deposited by electrolytic means, is made available for surfacing by this process. The development of metal-spraying in this country has been hindered by the war, but all indications point to an extension of the process in many directions when normal conditions are restored.

[Samples were exhibited at the lecture, showing the results of spraying metals on to wood, plaster and fabrics.]

A further use of the oxy-hydrogen flame is in connexion with the manufacture of articles from transparent silica. This material has a much higher softening temperature than glass, and cannot be worked in an ordinary blowpipe flame. Under the high temperature of the oxy-hydrogen blowpipe, however, silica articles of all kinds can be made readily, as the material may then be manipulated in the same manner as glass. There are also many minor operations in which the oxy-hydrogen flame is found useful, such as the autogenous soldering of metals, and in all cases where an ordinary blowpipe does not furnish the requisite degree of heat. A coal-gas flame, fed with oxygen in a blowpipe, is frequently used for the autogenous soldering of lead and other metals, and the temperature produced approximates to that of the oxy-hydrogen flame. The general use of coal gas for work of this type, however, is restricted owing to the impurities present. Attempts to weld cast-iron with coal-gas flame have met with a certain degree of success, and it is possible that this source of heat may find extended applications for special work, being cheaper than the oxy-hydrogen flame.

The Oxy-acetylene Flame.

When acetylene burns in oxygen, forming carbon dioxide and water, the following equation is realised :—

$$C_2H_2 + 5O = 2CO_2 + H_2O + 294{,}000 \text{ calories.}$$

If carbon dioxide and water were the only compounds present in the flame, the temperature attained could not exceed that of the oxy-hydrogen flame, and would probably be less, as the decomposition temperature of carbon dioxide is lower than that of water. The equation, however, only represents the final products of the reaction, and in practice the inner portion of the flame consists of carbon monoxide, which does not dissociate below 3000° C. An oxy-acetylene flame consists of an intensely luminous centre, containing free carbon, at the tip of which is a whitish cone in which carbon monoxide is largely present, and which is the hottest part of the flame. Round the inner flame is a layer of hydrogen, which at the temperature produced cannot combine with oxygen on the inner side, but which burns to form water on its outer side; and similarly the carbon monoxide burns to form dioxide in the exterior and cooler part of the flame. The temperature of the inner white tip approximates to 3000° C., being thus much hotter than the oxy-hydrogen flame, and this superior temperature, combined with other properties, renders the oxy-acetylene flame capable of performing operations of many kinds with ease, which can only be accomplished with difficulty, if at all, by other kinds of flame.

The cheap production of calcium carbide in the electric furnace has made possible the extended use of acetylene, and furnishes an example of how one high temperature process may give rise to another. The manufacture of carbide will be dealt with later; in the present connexion we shall only consider it in relation to the production of acetylene, which is formed

by the action of water on calcium carbide. There are two systems in use for producing acetylene—"water to carbide," in which a small quantity of water falls on to a mass of carbide, as in acetylene lamps; and "carbide to water," in which a small feed of carbide is supplied to a large mass of water. The latter method is preferable for generating sets used for welding and cutting, or for large-scale production generally, as the gas produced is cooler. The liberated gas contains impurities such as sulphur and phosphorus, which are removed by passing through a purifier before the gas is used for work on metals. Acetylene cannot be safely stored in cylinders under high pressure in the same manner as oxygen, but by using

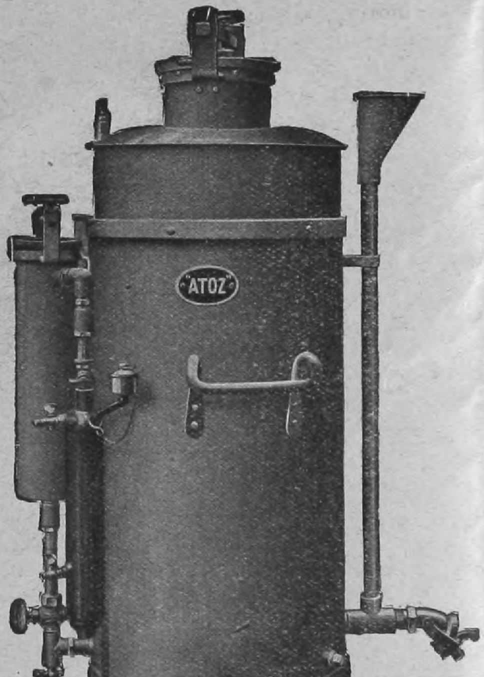

FIG. 1.—"ATOZ" ACETYLENE GENERATOR.

cylinders containing porous earths and acetone, large quantities of the gas may be compressed without danger, the acetone acting as a solvent, and the porous earths absorbing the gas. On opening the valve of the cylinder the acetylene escapes freely, its solubility in acetone and the quantity held in the pores of the earths diminishing as the pressure is reduced. Charcoal is frequently used as an alternative material for holding the gas under pressure. In high-pressure outfits, a cylinder of acetylene and one of oxygen are mounted side by side on a trolley for portability, both cylinders being provided with pressure gauges. In low-pressure outfits an acetylene generator replaces the cylinder, and provision is made to liberate the gas regularly only as required; a purifier, through which the gas passes, forming part of the apparatus. Amongst well-known equipments of this type are the "Atoz" generator (Fig. 1), which is of the "carbide to water" variety, and made by the Acetylene Corporation,

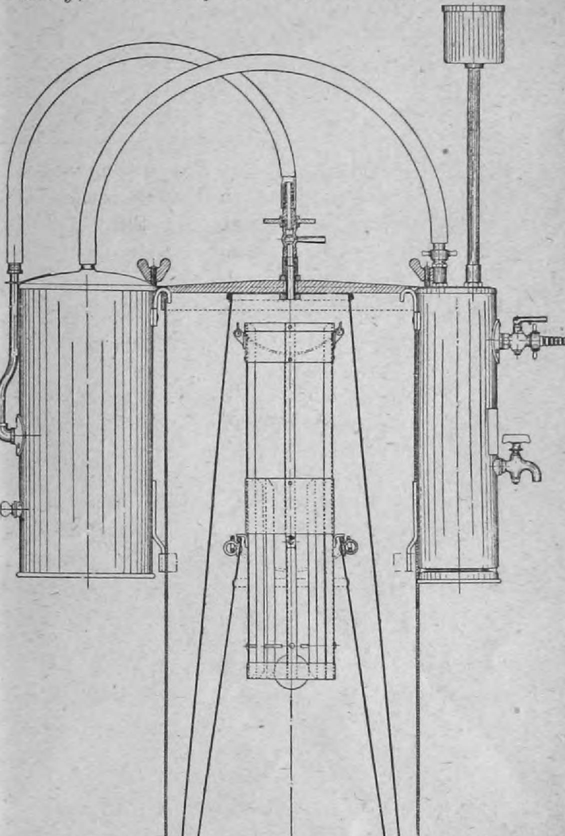

FIG 2.—"CARBIC" ACETYLENE GENERATOR.

Ltd.; and the "Carbic" generator (Fig. 2), made by Carbic, Ltd. In the latter apparatus cakes of prepared calcium carbide are used, in which the granules are coated with a material soluble in water, but impervious to atmospheric moisture, so that exposure to air does not cause decomposition as in the case of untreated carbide. In use, the cakes are suspended in a cage, and water is allowed to rise into contact with them, dissolving the coating and freeing the particles of carbide, which immediately

react with the water and liberate the acetylene. As the cake breaks up the pieces fall on to a fixed plate and there decompose; and when the escape-cock is turned off, the pressure of the gas forces the water away from the carbide, when generation ceases.

In using the oxy-acetylene blowpipe, the speed of exit of the gases should be from 100 to 150 metres per second; and this is secured on the high-pressure system by admitting both gases at a pressure of ·3 to ·4 of an atmosphere above the surrounding air pressure. In the low-pressure system, the entering oxygen acts as an injector, and is admitted at 1 to 1·5 ats. above atmospheric pressure, so that the mixed gases, before burning, possess the velocity stated above. Blowpipes used for welding contain a special chamber in which the gases are mixed before burning, and are provided with taps to regulate the supply of both oxygen and acetylene, so as to enable a flame of suitable size and character to be produced. This flame is made to impinge on the work, a rod of the metal undergoing welding also being held in the flame; and as both the work and the rod become thoroughly molten, a complete union is obtained. The free hydrogen round the working part of the flame is extremely beneficial in preventing oxidation, and enables a clean job to be made. When the material to be welded is massive, pre-heating is necessary in a fire or furnace, as the heat might otherwise be conducted away so rapidly that a satisfactory weld could not be obtained. Pre-heating always leads to economy in gas, and is generally resorted to in cases where the thickness of the material to be welded exceeds ¼ inch. The consumption of gases in welding iron plates, without pre-heating, is shown in the following table:—

Approximate thickness of plate joint		in. $\frac{3}{64}$	in. $\frac{3}{32}$	in. $\frac{3}{32}$ to $\frac{1}{8}$	in. $\frac{1}{8}$ to $\frac{3}{16}$	in. $\frac{3}{16}$ to $\frac{9}{32}$	in. $\frac{9}{32}$ to $\frac{3}{8}$	in. $\frac{3}{8}$ to $\frac{1}{2}$	in. $\frac{1}{2}$ to $\frac{5}{8}$	in. $\frac{5}{8}$ to $\frac{3}{4}$
Approximate consumption of gas per hour	Oxygen	c. ft. 4·25	c. ft. 7·5	c. ft. 12·0	c. ft. 17·0	c. ft. 25·0	c. ft. 37 0	c. ft. 60 0	c. ft. 85·0	c. ft. 125·0
	Acetylene	c. ft. 2·5	c. ft. 4·5	c. ft. 7·0	c. ft. 10·0	c. ft. 15·0	c. ft. 22·0	c. ft. 35·0	c. ft. 50·0	c. ft. 75·0

The time required to make a welded joint of given length depends upon the skill of the workman and the character of the work; but in an average case a weld on plate of ⅛ inch thickness should be carried out at the rate of 14 feet per hour; if ⅜ inch thick, 6 feet per hour; and ½ inch thick, 4 feet. For plates above ¼ inch thick, pre-heating reduces the time and cost by 30 to 50 per cent.

During recent years great progress has been made in applying the oxy-acetylene flame to the welding of non-ferrous metals and alloys, such as aluminium, copper, brass, bronze, etc., and the process has proved particularly useful in the case of aluminium, which cannot easily be joined by other means. In connexion with the production of munitions of war oxy-acetylene welding has played a very important part, and thousands of workers of both sexes have acquired great proficiency in this class of work. Another important application of oxy-acetylene is in the cutting of iron or steel plates. Fletcher discovered, many years ago, that if an iron plate were heated by an oxy-coal gas flame, and the supply of oxygen largely increased, holes and slots could be burnt out of the plate. In a modern blowpipe, as used for cutting iron, an additional passage is provided for a separately-controlled jet of oxygen, which may be made to impinge on the work. This jet, for example, may issue from a central tube, whilst the gases used for the flame are fed into the surrounding annulus. By this arrangement the work is heated to the necessary temperature by the flame, and converted into fluid oxide by the oxygen issuing from the central tube. The oxygen used for cutting is at a higher pressure than when employed for welding, and blows away the fused oxide through the cut, so that the operation is continuous. As the flame is only required to keep the work hot, the proportion of acetylene to oxygen used is much less than in the case of welding. The distance between the cutting nozzle and plate is maintained at about ¼ inch, and the size of the flame and the pressure of the jet are varied according to the thickness of the work. With a plate 1 inch thick, and a nozzle pressure of 14 lb. per square inch, a cut 40 feet in length can be made in one hour, with an oxygen consumption of 90 cubic feet. For a plate 1 foot thick, 1,760 cubic feet of oxygen are needed to cut a length of 16 feet in one hour, with a nozzle

pressure of 55 lb. per square inch. Plate-cutting by this process has almost entirely replaced cutting by steel tools in the case of boiler and ship repairs, and is now firmly established as a workshop process. Apart from cases in which operations involving the oxy-acetylene flame are continuously carried out, outfits for incidental work may now be found in almost every engineering establishment, and their use is continually extending. A monthly publication, the *Acetylene and Welding Journal*, is now issued, devoted to this industry.

The Electric Arc.

Everyone is familiar with the result obtained when two rods of conducting material are touched and a powerful electric current passed through them, when the rods may be drawn apart for some distance and the current maintained through the vapourised material which fills the gap. The limit of temperature attainable is decided by the vapourising point of the conductor, and using carbon, a temperature of 3700° C. may be reached which exceeds that obtainable by any other means by 700°. The use of the electric arc in furnaces will be considered later, but its application to welding may be conveniently dealt with at the present stage. In early attempts an arc was struck with carbon electrodes in proximity to the work, and fed with iron, but in this form the process was only moderately successful. A later development consisted in the use of a single carbon rod, with which an arc was formed by connecting the work to the source of current, an iron rod being fed into the arc as before; and this method is still in use for manufacturing seamless steel drums and pipes. The latest type of arc-welding, due to Albrecht and Dantz, is effected by using the work as positive electrode, and an iron rod as negative. In practice the iron rod is about $\frac{1}{8}$ inch in diameter, and is coated with a flux, and the welder strikes an arc between this and the spot to be operated on, maintaining a distance of about $\frac{1}{4}$ inch between the rod and the work. A powerful current is used, and as the rod melts the metal is carried through the arc and deposited on the work, the joint being hammered from time to time whilst at a welding heat. This is continued until the requisite quantity has been deposited, and owing to the high temperature of the arc a complete union is secured. A skilful welder can thus make a joint in the roof of a boiler, the iron from the arc adhering to the work, and not, as might be expected, dropping down in a molten condition. Arc-welding is thus specially useful for awkward places which could not easily be got at by other appliances; and in addition welds may be made in heavy masses without pre-heating, owing to the high temperature of the arc. Arc-welding is now extensively used in connection with repairs to ships, being applied to filling in cracks in boilers, flues, tanks, wheels, etc., and for restoring the metal in holes caused by corrosion. Figs. 3 and 4 illustrate a repair to the end-plate of a marine boiler carried out by the British Arc Welding Company, Fig. 3 showing the crack, and Fig. 4 the finished weld. Portable generating sets are made which may be used when power mains of suitable voltage are not available, and in this manner arc-welding may be carried out on a ship lying in harbour. Large steamers frequently carry an outfit for effecting repairs whilst afloat. A further useful application of arc-welding is the

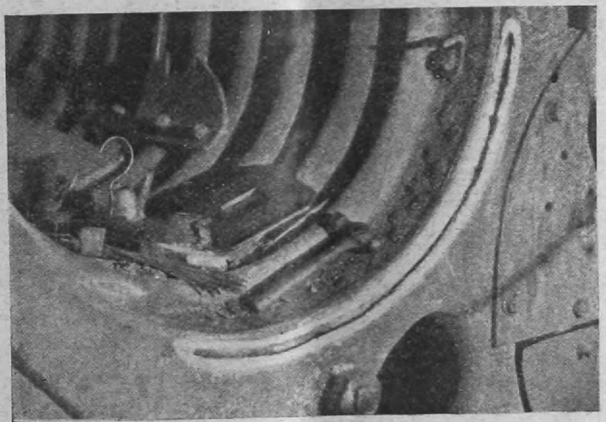

Fig. 3.—Crack in Boiler before Arc-welding.

filling of holes in tram rails, and the restoring of parts worn away by the abnormal friction at crossings. Fig. 5 shows the outfit provided for this purpose by the Equipment and Engineering Company, the head of the welder being covered by a hood in which tinted glasses are inserted to enable the progress of the work to be seen. The current in this case is taken from the tramway supply, being transformed to the correct voltage by means of a motor-generator. The saving effected in this case is manifest, as the alternative to the repair would be the renewal of the rail.

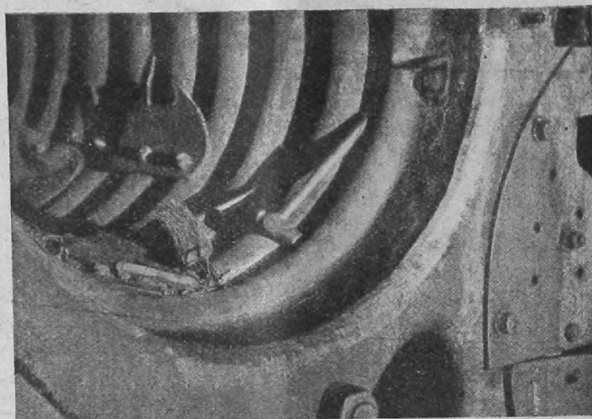

FIG. 4.—THE FINISHED WELD OF THE CRACK SHOWN IN FIG. 3.

Electric welding has for many years been applied to the joining of rods of iron or steel, as an alternative to fire welding. In this case the ends to be united are brought together, and a strong current passed through the contact. Heat is developed partly by arcing, and partly by the high resistance due to imperfect contact; and when a welding heat is attained the two portions are squeezed together and thus caused to unite. This method has been applied to large sections, for example, the jointing of consecutive rails on tramways, but is generally restricted to smaller classes of work. A method of joining wires to one another, or to plates of metal, has recently been experimented with in the United States, and is called "electro-percussive" welding. The wires are gripped in suitable jaws, with a small portion protruding, the lower jaw forming the base of a vertical frame down which the upper jaw may be dropped, the force of the impact being applied to the ends of the wires. The wires are connected to a charged battery of condensers, and when the upper jaw is allowed to fall a powerful spark is produced at the moment the wires come into contact; the heat generated, combined with the blow, causing the ends of the wires to weld together. If the lower wire be replaced by a plate of metal, the upper wire is welded to the place where it strikes. In this manner a tin wire may be welded to platinum, although their melting-points differ by more than 1500° C., and the process gives promise of application in many directions.

[A demonstration of oxy-acetylene welding and plate-cutting was given at the lecture by Captain D. Richardson, R.F.C.]

WATER-POWER IN THE BRITISH EMPIRE.

An interesting and important preliminary report of some thirty pages has been issued by the Water-power Committee of the Conjoint Board of Scientific Studies. The Committee, of which Sir Dugald

Clerk, K.B.E., F.R.S., is Chairman, and Professor A. H. Gibson, D.Sc., Secretary, was appointed "to report on what is at present being done to ascertain the amount and distribution of water-power in the British Empire." With this in view the Committee proceeded to collect all available relevant information. The report says:—

"The results have been both encouraging and disappointing. Encouraging because, in spite of the meagreness of the information regarding vast stretches of the Empire, sufficient data are available to show that its water-power resources are in the aggregate enormous; disappointing because, with the exception of Canada and New Zealand, Tasmania, New South Wales, and possibly South Africa, practically nothing has been or is being done on any systematic basis, to ascertain its true possibilities...

"To enable the Empire to recover, with any degree of rapidity, from the financial burden imposed by the war, it will be necessary to develop, in a much greater degree than heretofore, its latent resources. The wealth embodied in its mineral resources, its wheat areas, its forests, and the hundred products of its tropical dependencies, is almost incalculably great. But it must be realised that without an ample supply of cheap energy much of this wealth must always remain latent.

"Energy is required to enable the mineral ores to be won and refined. It is required for the adequate fertilisation of the land, as well as for the harvesting and transportation of its crops and products; and any scheme for the extensive development of the Empire's resources as a whole, must depend upon the preliminary development of its energy supplies."

The world's present power demand is estimated at, approximately, 120 million h.p., of which between 15 and 16 millions is developed from hydraulic resources. In respect to the latter, the United Kingdom is, with one exception—Russia—the most backward of twelve countries enumerated, our percentage being 8·3, against Germany's 43·4.

So far as the Dominions and Dependencies are concerned, it is fairly certain, the Committee says, that in Canada, India, New Guinea, and New Zealand alone there is a potential water horse-power of the order of 40 millions. Adding the resources of Africa (East, South and Central), Egypt, Ceylon, Australia (including Tasmania), British Guiana, Burma, the Malay States, and the British Isles it appears that in the aggregate the hydraulic resources of the Empire are extremely large and that they are as yet barely tapped.

The developments in engineering science in the past decade, and more particularly those in electro-chemical, electro-physical and electro-metallurgical processes, and in the possibility of high voltage electrical transmission, have removed some of the reasons for past neglect.

Special reference is made by the Committee to the utilisation of atmospheric nitrogen for the production of nitric acid and the manufacture of nitrates. The annual consumption of nitrogen in its various combinations is about 750,000 tons, and the need increases yearly.

"Four-fifths of this supply has been produced hitherto from natural nitrate deposits, but in view of the rapid depletion of these deposits, and of the diminution in the fertility of most of the great wheat and cotton-growing areas of the world, the production of artificial fertilisers by one or other system of nitrogen fixation must, in the near future, become a question of national importance.

"At the present time the world's consumption of fertilisers amounts to close upon 6,000,000 tons per annum, and this will probably be doubled within the next twenty years. To-day, the efficiency of the electrical production is low, amounting in the case of calcium nitrate to about three-quarters of a ton per e.h.p. year. By adopting the cyanamide process the consumption of energy may be cut down to about one-fourth, but even in this case the production of the equivalent of 12,000,000 tons of fertilisers per annum would require 4,000,000 continuous e.h.p.

"It is estimated that the 200,000,000 acres of arable land in Canada alone may ultimately require some 10,000,000 tons of nitrates per annum to maintain their fertility, and this in itself would necessitate the absorption of an appreciable portion of the whole hydraulic energy of the Dominion.

"When to these demands are added those of India, Australia and Africa, it is evident that the fertiliser demand of the Empire will in itself call for an enormous supply of energy."

After a general indication of the water-power possibilities of the separate parts of the Empire, the main conclusions drawn from the evidence available to the Committee are stated to be:—

"1. That the potential water-power of the Empire amounts in the aggregate to at least fifty to seventy million horse-power.

"2. That much of this is capable of immediate economic development.

"3. That except in Canada and New Zealand, and to a less extent in New South Wales and Tasmania, no systematic attempt has as yet been made by any Government Department to ascertain the true possibilities of the hydraulic resources of its territories, or to collect the relevant data.

"4. That the development of the Empire's natural resources is inseparably connected with that of its water-powers.

"5. That the development of such enormous possibilities should not be left to chance, but should be carried out under the guidance of some competent authority."

The Committee concludes its report by submitting the following recommendations:—

"1. That the British Government bring before the notice of the Indian Government, of the various Dominion Governments and of the Governing Bodies of the Crown Colonies, the necessity for a close systematic investigation of all reasonably promising water-powers, and of their economic possibilities.

"2. That the British Government take steps to ascertain whether the Governments concerned are prepared to undertake this work.

"3. That where such an inquiry is beyond the powers of any governing body, the British or Imperial Government place the work under the direct control of an 'Imperial Water Power Board' or 'Conservation Commission.'

"4. That the Government take steps to initiate the formation of such an 'Imperial Water Power Board' or 'Imperial Conservation Commission,' to include a representative from each of the Dominions and Dependencies.

"5. That this Board act in an advisory capacity.

"It should decide on the sequence of such investigation work as comes under its purview.

"It is suggested that all schemes for the development of which local resources are inadequate, should be submitted to the Board by the governments concerned, and that the Board should make recommendations on which the Imperial Government might take action.

"Such a Board would be able to take a broad and comprehensive view of the advantages to the Empire as a whole, attending the development of any given scheme, and would be able to form a reasonable decision as to the relative advantages of such different schemes as might be brought forward from different parts of the Empire.

"6. That since it is unlikely that private capital will be available for many years for hydraulic development on any large scale, powers should be obtained to enable the State to assist or to undertake such development if thought advisable.

"It is suggested that much might be done to attract private capital, if the State, after careful investigation, were to guarantee a suitable minimum interest on the necessary capital, sharing at the same time in any profits beyond the amount necessary to provide that interest. By this method of assistance private enterprise would be untrammelled, and the management of the concerns so assisted would remain in private hands."

CHINESE WOOD-OIL VARNISH.

The manufacture of kwang yu (literally "lustrous oil"), as practised by the Chinese, is very simple. T'ung yu, or wood-oil, is used as the base for this varnish, and two mineral substances, known as t'utzu and t'o-shen, are added. The process usually takes about two hours. The first step is to boil the wood-oil in large iron vats. Once the substance has begun to thicken, the mineral substances mentioned are added in proportions of one ounce of each for every catty of oil (catty = 1⅓ lb.).

As much of the wood-oil arrives on the local market containing a small percentage of water, it is necessary to use some substance which will free the oil of this adulterant. T'utzu, which is a ferruginous clay, serves this purpose by absorbing the water content. When the t'utzu is added, the liquid boils furiously, and at times, if the heat is too great, it bursts into flames. When this condition arises, a small percentage of linseed oil is added, and immediately forms a covering film, which smothers the flames.

T'o-shen, which local mineralogists state is native red lead, is added to the boiling oil at the same time as the t'utzu. This product is used to give the resulting liquid the proper colour, and to prevent it becoming cloudy or unequal in density. Before it is ready to be added to the wood-oil, it must be finely ground. This is accomplished by small hand crushers, which are usually made of stone.

It is impossible, writes the United States Vice-Consul at Hankow, to state the degree of heat that must be reached before the mineral substances are added, as the natives who manufacture the varnish have no set rules for the work. The point at which the liquid begins to thicken is considered the correct one, and from this point the boiling process is allowed to continue without further interruption until the oil finally reaches the consistency of varnish. This usually takes about two hours, although the amount of liquid in the vat and the size of the fire may materially alter the length of time required.

Kwang yu is used by the natives as a waterproofing substance for silks, pongees, etc., and also as an ornamental varnish when various colouring materials are added. It should not be confused, however, with the well-known lacquer varnish of China and Japan which, according to an authority on the subject, is gathered in its crude state from the *Rhus vernicifera* or che shu tree, and which is used for very different purposes.

THE "GO-TA-NI" BEAN.

Attention is drawn by the United States Consul at Mombasa to the production in East Africa of a new kind of bean, called the "go-ta-ni," which is described as yielding two crops per annum, with high percentage of albuminoids and oil, while the moisture is low. The owner of the estate at Changamwe, where the experiments have been made, calls the product a cross between the Madagascar butter bean and the *Canavalia ensiformis*. It is credited with a yield of 22 cwt. of dried marketable beans per acre during the 1916 season. The *Mombasa Times*, in an article on the subject, gives the following details:—

"The period for maturing is five months. The plant is a standard perennial, and attains an average height of 2 ft. 6 in. It is extremely hardy, being both a drought and insect resister. The foliage is dense, and if planted 1 ft. apart in drills, the rows being 3 ft. apart, it entirely prevents the growth of weeds. At this distance 63 lb. of seed will plant an acre. The seed readily

germinates. When 6 in. high the ground should be hoed, after which the plants require no attention until the crop comes off. Planted between young coco-nut palms, coffee, sisal, etc., they do away with at least two cleanings per year, while their foliage offers excellent shade and protection to the young plants.

"The pods attain a length of 14 to 16 in., and yield 14 to 16 perfect beans, which are ⅞ by ½ to ½ by ⅜ in. in two dimensions and ⅛ in. thick. They are white externally, the hilum being brown. The interior is a pale yellow, and they possess an agreeable flavour. On a sample sent to England £18 per ton was offered. This works out at £19 16*s.* per acre every six months. As the crop can be picked, thrashed and bagged on the land, it should prove one of the most profitable products grown in the Colony.

"The advantages of a perennial legume of this nature are manifold and cannot be overestimated. For planters it reduces the tremendous cost of cleaning to a minimum and brings the plantation into an almost immediate paying concern. It gives a good return in six months with very little outlay.

"There is nothing in the chemical analysis to indicate that the material is unfit for food; on the contrary, the beans should provide a nitrogenous food of a concentrated kind, the protein content being nearly equal to that of dried beef. No prussic acid has been detected in the macerated product, nevertheless, if the material has not been used before as food for human beings or animals, it would be advisable to ascertain by experiment that no poisonous substance is present."

CHINESE TRADE IN HUMAN HAIR AND HAIR-NETS.

From a report by the United States Consul-General at Shanghai, it appears that some of the hair used in hair-nets purchased by women in the United States has crossed the Pacific Ocean three times before reaching retail dealers. This results from the fact that a considerable part of millions of pounds of human hair exported from China finds its way back again, after preparation, for use in the manufacture of hair-nets—the so-called "invisible" nets worn by women over their hair. The hair-net business has become of great importance to the Province of Shantung, which now provides practically the entire supply of Europe and America, Germany and Austria formerly having had a monopoly of this trade. Nets were first made in Shantung under the direction of German firms.

According to the accepted trade explanation of the growth and development of this kind of business in China, it is understood that hair-nets were originally shipped by German parcel post to small villages in Germany, thence to Strassburg, the centre of the trade. The source of supply of those cheap nets was kept secret for three years.

In 1914 London began to buy direct from Chefoo, in Shantung, and for a while controlled the European and American trade. Later, France became active in the business. The market for hair-nets is now, however, being rapidly diverted to the United States.

On November 20th, 1911, after the downfall of the Manchu dynasty, a resolution was adopted in favour of the abolition of the queue. This was followed by the wholesale cutting of queues, not, however, to the extent generally imagined. In many parts of south and middle China the queue has practically disappeared; but the bulk of the populace in North China still wear it, and it is probable that many million queues will continue to be worn in China for an indefinite period.

The exportation of human hair from China, however, has grown greatly in importance during the last decade. Shipments for 1914 and 1915 fell far below those for the preceding four years, but this is probably attributable not to decreased demand but rather to the difficulty of procuring the hair.

Exports from China of human hair from 1910 to 1915 were as follows: 1910, 3,523,933 pounds; 1911, 2,583,867 pounds; 1912, 3,259,600 pounds; 1913, 3,667,867 pounds; 1914, 1,926,800 pounds; 1915, 1,919,200 pounds.

Estimating the weight of a Chinaman's queue to be 3 ounces (the reported average of 500 weighed queues), the number of queues required to make up the above shipments for six years would be more than 90,000,000, which is approximately half of the estimated male population of China, including queueless infants. As most of the older Chinese who still have queues will probably continue to wear them, and as new generations of even the most conservative will doubtless gradually drop the queue, there is likely to be increasing difficulty from year to year in obtaining sufficient human hair to meet the demands of the trade. However, dealers are not wholly dependent upon the queues of men for their supplies of hair.

Since 1912 and 1913 the queues of men have not been readily obtainable, and the hair-dealers are becoming more and more dependent upon the combings of women. Men who have dispensed with the queue in a good many instances allow their hair to grow to a length of 8 inches or more, and such lengths when cut are saved by the barber and sold to the small trader in hair. These small dealers make regular calls at barbers' shops and canvass the homes of the Chinese, collecting cuttings and combings and an occasional queue, all of which find their way finally to the central markets, where they are taken in hand by the wholesale dealers. Many poor women sacrifice their hair in times of stress, and large numbers of them during periods of flood and famine.

Hair is prepared for export in some markets by tying it into bundles containing hair of approximately the same length. The lengths run from 8 to 36 inches. In other markets bundles are formed containing proportionate quantities of hair

of the various lengths. Most of the exports go to England, France, and the United States, where the hair is manufactured into switches, curls, bangs, wigs, etc., of such colour as may be desired. The process is a delicate one, requiring expert judgment. Generally and briefly, it consists of bleaching by peroxide, thinning by acid, and boiling in dye. As a result the hair becomes finer in texture and softer than it was originally, and incidentally cleaner and more sanitary, since any one of the processes is sterilising.

The hair of certain animals, such as the yak, goat, and others, is mixed by the manufacturer with human hair to a certain extent. The hair of a white yak's tail is particularly valuable, not only because of its length, but also because of its whiteness, which, mixed with other shades, produces the desired silvery effect.

WEED DESTRUCTION IN SUGAR-CANE FIELDS.

A process of destroying weeds in canefields has been recently devised and developed by Mr. C. F. Eckart, manager of a sugar company in Hawaii, with the result that less than one-half of the labour formerly required is needed on the treated areas to bring the cane to maturity. In addition to the large saving in labour, the increased yield of cane as a result of the treatment, it is estimated, averages ten tons per acre.

Mr. Eckart found that small unexpanded cane shoots were able to penetrate a suitable paper covering placed directly on the rows of stubble immediately after harvesting, whereas the weeds are unable to penetrate it. According to a report by the Correspondent at Honolulu of the United States Department of Commerce, the first step in this process is to "palepale," or free the rows of trash in the ordinary way, as soon after harvesting as possible. During this operation a point is made to cut off with the hoe any shoots which are in evidence in the cane row. The stubble rows are then fertilised, the fertiliser being distributed along the middle of the rows. Strips of tar or asphalt felt (weighing not more than 9 lb. per 100 square feet) are next placed longitudinally on the rows of stubble, so that they lie directly in surface contact with them in the form of a cover. If the field contains a fair number of stones or rocks which are conveniently at hand, these are placed along the edges of the paper strips to hold them down, and in addition the edges of the strips are also covered well with some of the dried cane leaves or trash lying in the adjacent spaces between the cane rows. It has been found that the trash is generally sufficient in itself to hold the papers in place against the tendency of the wind to lift them.

Owing to the spearlike and comparatively rigid nature of the young cane shoots, and the mechanical pressure they are able to exert when they come into contact with the paper covering, the latter is punctured and the shoots emerge. The weeds, with their relatively soft terminal points, are soon smothered out, or are dried up by the solar heat radiating from the underside of the covering.

Five or six weeks after the paper coverings have been applied, labourers pass along the cane rows, and with a knife cut longitudinal slits in the paper at such places as are under pressure from expanded shoots, these places being distinctly manifested by the tentlike elevations. The slitting is inexpensive, and costs about 35 cents. an acre in practice. At first these shoots are naturally quite etiolated, but they quickly turn green and take on a vigorous growth.

The right kind of paper must be used. Of the many papers that have been tried in this process, the best is a lightweight tar or asphalt felt. The common black sheathing felt, weighing 9 lb. to 100 square feet, is to be preferred above all others which have been tested. Possibly a lighter felt might prove even more suitable, since the 9 lb. paper is the lightest that has been tried.

The large gain in the growth of the cane in this process is due to the automatic eradication of weeds in the cane rows and to the pronounced mulching action of the paper covers. Being black and impregnated with such material as tar and asphalt, they absorb a large amount of heat, which they impart to the soil of the cane rows.

Mr. Eckart's company is contemplating the erection of an auxiliary paper-mill of sufficient size to meet the demands of the fields for paper mulches. The raw material for the manufacture of paper would be a part of the bagasse from the crushed cane, and the mulches could be turned out at comparatively small cost.

AN AMERICAN PORT IN FRANCE.

In an article, entitled "Le gigantesque effort de nos alliés en France," *Le petit niçois* gave an interesting account of the extensive harbour works now in course of construction "somewhere in France" by our Allies the Americans.

From this we learn that upwards of 2,000 acres of land, which less than a year ago was mostly marshes, is now being transformed, almost by magic, into a port of the most modern type, provided with up-to-date appliances and machinery for discharging the cargoes of vessels of the largest tonnage.

An army of about 12,000 men is engaged in the construction of the docks, quays, and warehouses. Already large vessels are daily discharging their cargoes of warlike stores of every description by means of electric cranes. The new dock is being dredged and extended so as to berth at the same time fifty or sixty ships of large tonnage. About 100 miles of railway sidings have been laid down, to connect the new port with the principal main lines in that part of France.

A hospital, to contain upwards of 20,000, is also being built, and no time is being lost to make this new port one of the best equipped in the world, with all that is necessary for the rapid discharge of military stores, as well as for the landing of troops and artillery.

RECENT TESTS OF CONCRETE COLUMNS.

Among the tests conducted recently by the United States Bureau of Standards as aids to the development of industrial methods were series relating to the construction of concrete columns and the production of insulating material.

Three tests were made of a special commercial insulating material to determine its pre-resisting properties. The material submitted by the manufacturers was intended for use in a number of instances to replace wood. The test specimens were about 18 in. by 18 in. and 6 in. thick. They were placed in a furnace as a panel, one of the larger faces being exposed to the heat of the furnace and the other to the atmosphere. Upon being heated to 950° in 30 minutes and held at that temperature for four hours, it was found that the temperature at a distance of 1½ in. from the heat-exposed surface was about 240° C. At a depth of 5½ in. from the heat-exposed surface 66° was the highest temperature recorded. One of the blocks after having been subjected to this heat for the period mentioned was quenched with water. The damage to the specimen that was quenched was found to be less than to an unquenched specimen. This is explained by the fact that the blocks contained considerable organic matter, which tended to be disintegrated by the heat transmitted very slowly from the heated surface, even after the flame was removed from it.

The series of tests of concrete columns was partly in the nature of an investigation and partly in the nature of routine testing. These were the first columns of their kind to be tested in the United States. The unique feature is a hollow cast-iron core. This is surrounded by concrete, reinforced with both spiral and vertical reinforcing. Such a column may be made very cheaply. It would appear that the load which these columns can sustain is considerably in excess of that which can be borne by the ordinary reinforced concrete column of an equivalent cross-section.

ENGINEERING NOTES.

The Inventor of the Locomotive Engine.—A London daily newspaper has been taken to task for referring to the invention of the locomotive as due to Stephenson. It was in 1808 that the first engine, drawing a load behind it, was put on the rails by Richard Trevithick, many years before the first public railway was begun, for they were slow in those days; but it must be admitted that there was a British war during the interval. Stephenson, by his "pushfulness" and the sensational introduction of the "Rocket," was only following the improvements which Trevithick and many others had made. The compound and superheater methods, and those of many others, had no more godfathers than had the Northumbrian mechanic.

The Wilson Bridge over the Rhone at Lyons.—On July 14th a handsome bridge over the Rhone was inaugurated. The construction commenced shortly before the outbreak of war, and was carried on, notwithstanding the disturbance to public works which the hostilities have entailed. The *Génie Civil* of July 13th publishes an illustrated and detailed account of the work, of which a summary only can be given here. The bridge is of four main masonry arch spans, externally treated in pairs, 42, 45, 49, and 45 metres respectively, and two approach spans of 7·50 and 11 metres, on an inclined grade. The length over all is 226·30 metres. The width between parapets is 20·10 metres, comprising a carriage-way of 11 and two footways of 4·55 metres each. The internal space between the masonry arches, which are of perforated design, is of cross steel girders, supporting a floor of reinforced concrete and wood-paving. In a subsequent issue of the same journal, M. A. Auric criticises the design as regards the cross girders, stating, in his opinion, that steel girders ought to have been replaced by reinforced concrete ones, and that, with this in view, a pair of carriage-ways, right and left, over the stone arches ought to have been provided, leaving the single footway in the centre, to be supported by the reinforced concrete cross girders.

Quebec Dry Dock.—This dock, said by the *Engineer* to be the largest in the world, was begun in 1914 and has just been completed. The length is 1,150 ft., the breadth 120 ft., and depth over high water 40 ft. It is divided into inner and outer compartments, 650 and 500 ft. respectively. Centrifugal pumps are used, and 63,000 gallons per minute pumped against a head of 25 ft.; 550-volt Curtis turbo-generators, using 2,550 kilowatts, are employed. The filling takes four and the emptying 2½ hours. It is a notable fact that this enterprise, as well as an important large bridge, already referred to, over the Rhone at Lyons, should have been begun and ended practically simultaneously in war time.

Coal in Algeria.—The recent discovery of a bed of anthracite coal of considerable extent near Bona, in Algeria, has, says the *Electrical Review*, attracted the attention of the French Government, which has now taken over the working of the coal beds. The anthracite is stated to be equal to the best Cardiff coal, and to be sold at a price not higher than 150 lire per ton. Exported to Italy, its price would be about 210 lire per ton, and the first consignment of 30,000 tons will be ready for shipment shortly. Many Italian electric undertakings have been compelled to suspend working in consequence of inability to obtain imported coal, and the present opportunity is hailed with much satisfaction.

Paper Pulp.—In the manufacture of wood pulp for paper there are two essentially different methods: one, the mechanical system, which is

comparatively simple, and, secondly, the chemical systems, which require greater skill and knowledge in the operating staff. The latter systems are largely employed in Scandinavia, while the Colonial and American pulping plants are worked on the mechanical system. The wood generally used in the manufacture of wood pulp by the mechanical process is white pine or poplar. The wood is cut into slabs of a convenient size, which are then pressed against the face of a millstone revolving at a high speed, while a flow of water conveys the fibres of wood away as they are separated. The chemical processes, known as the sulphate and sulphite systems, are much more elaborate, and the pulp produced is used in the manufacture of printing and writing paper of superior quality.

An Electric Precipitation Process for obtaining Potash.—According to the *Journal of Electricity*, this process has enabled the United States cement workers to obtain potash from the residue dust. In one case a year's trial, under practical operation, has ended in the rather astonishing result of a greater income from potash than from cement. Operating costs show conclusively that the process will be profitable at pre-war prices, and that a supply of potash for fertilisers as well as for ammunition is now assured.

Indian Portland Cement.—A report, issued by the Indian Government, of tests by Mr. Musgrave, Alipore, states that he finds that Indian Bundi and Katni cements, as at present manufactured, are equal to the best English brands, also that the same is true of Porbandar cement, except as regards its tensile strength, which is somewhat low. All these cements are sound, reliable, and suitable for every class of work. Imported cements are not infrequently found to have deteriorated during a voyage, and Indian cements offer advantages in this respect also. When the article has to be conveyed long distances by rail from the factory to the consumer, the freight charges add greatly to the cost, and for this reason it is desirable that cement factories should be distributed over the country as widely as possible.

GENERAL NOTES.

CONCRETE STANDARD AND FABRICATED SHIPS.—Lord Pirrie, Controller-General of Merchant Shipbuilding, in the course of a statement he made on August 8th, referred to the steps taken to secure the present marked acceleration in output. He continued: "We have recently begun the building in this country of small concrete ships. These ships are being constructed, for the most part, in large wooden moulds (technically known as 'shuttering'), into which the steel rods for reinforcement are placed, and the concrete is afterwards poured in. We have at present fifty-six concrete vessels actually under construction, and have made arrangements for numerous other vessels to follow. The advantages of standard ships are that repeat vessels can be constructed with greater ease, and all the machinery and auxiliary fittings for each type of ship are interchangeable. Twelve months ago the number of standard ships under construction was 26 per cent. of the total, and to-day this proportion has increased to 74 per cent. The fabricated ship carries the principle of 'standardisation' considerably further. This type of ship was originally designed for the national yards, but private shipbuilders have asked to be allowed to build them, and already we have eleven fabricated ships on the stocks in private yards, for which units are being used which were originally ordered for the national yards."

INDUSTRIAL OUTPUT.—According to a correspondent of *The Times*, the output of coal to-day is less per man than it was before the war. It is sixty tons per man less than it was thirty-five years ago, when machinery, tools, lights and ventilation were not to be compared with what they are now. Dr. H. M. Vernon, of Oxford, writing to the same journal, mentions that in one of a number of yards in our two chief shipbuilding centres visited by him the riveters engaged on a very large oil ship were found to put in 15 per cent. less rivets per hour than they did in 1913 when engaged on the same type of ship, and when working the same weekly hours. In another yard, where standard ships of moderate size have been built for many years past, the rate of riveting was accurately investigated from 1903 to 1906, and was found to remain nearly steady throughout this period, both in summer and winter. From July to December, 1917, however, riveting squads on the same type of ship put 28 per cent. less rivets per hour than in the previous period, and in January to March, 1918, they put in 31 per cent. less. The other workers had deteriorated less than the riveters, but the platers showed a 20 to 25 per cent. reduction of output.

BRITISH SUGAR INDUSTRY.—The West India Committee have been informed that the Government have decided to give to the signatories to the Brussels Sugar Convention the requisite six months' notice of their intention to resume complete liberty of action in respect of their policy with regard to sugar. When the British Government withdrew from the Brussels Sugar Convention in 1913, they gave a pledge to the signatories not to give a preference in the duties in the market of the United Kingdom to sugar from British Colonies, or to cane sugar over beet, without six months notice. The West India Committee have constantly urged that such notice should be given immediately in view of the desirability of taking steps to secure the development of the British sugar industry, and to render the British Empire self-supporting in respect of its sugar supply.

CANTOR LECTURES.

HIGH TEMPERATURE PROCESSES AND PRODUCTS.

By Charles R. Darling, A.R.C.Sc.I., F.I.C.

Lecture II.—Delivered January 28th, 1918.

Thermit.

More than half a century ago attempts were made by various workers to utilise practically the reducing power of aluminium. In these early experiments mixtures of oxides and metallic aluminium were heated by external means until the reaction commenced, with the general result that the crucible was destroyed, and occasionally the furnace also, owing to the extreme violence with which the chemical action took place. It was not until early in the present century that a means was found to apply this property of aluminium to industrial purposes, the credit for which is due to Goldschmidt, who originated the plan of igniting the mixtures at a point, with the result that the reactions proceeded more slowly, and without destructive effects. Goldschmidt, taking advantage of the high temperature produced, applied mixtures of aluminium and oxide of iron to the purpose of welding; and also used other mixtures for the production of metals such as chromium and manganese. The name "thermit" was applied to such mixtures, and at the present time thermit processes are largely used for a variety of purposes.

The intensely high temperature produced when an oxide is reduced by aluminium is due to the large heat of formation of aluminium oxide, which for 1 gram-molecule is 393,000 calories. Ferric oxide (Fe_2O_3) is formed from 112 grams of iron with the evolution of 196,000 calories. Consequently, in the reaction

$$Al_2 + Fe_2O_3 = Al_2O_3 + 2Fe,$$

the surplus heat of formation of aluminium oxide over iron oxide is liberated. The reaction proceeds so rapidly that practically the whole of this heat is utilised in raising the temperature of the products, radiation and conduction losses being small in the short time occupied. The actual temperature produced varies with the oxide used, but generally ranges from 2500° to 3000° C. As iron melts at 1500° C., and aluminium oxide at about 2000° C., both products of the reaction are fluid, and when contained in a crucible the iron sinks to the bottom, leaving the fluid alumina as a slag at the top. A similar result is obtained when other oxides are reduced.

One feature of thermit reductions is that the reaction does not commence below 1100° C., and hence a thermit mixture may be thrown on an ordinary fire without igniting. To start the combustion, a small quantity of ignition mixture, consisting of powdered aluminium and barium peroxide, is placed on the top of the thermit and lighted with a match, the temperature thus generated sufficing to commence the burning of the thermit. When once started the reaction spreads rapidly through the mass.

The welding of iron and steel now constitutes one of the chief applications of thermit industrially, and in many cases this form of welding is preferable to any other. A common example is furnished by tramways, the consecutive rails of which are frequently welded together by thermit. In this case a suitable mould or frame, lined with a refractory material, is placed round the joint, and an arrangement is attached by means of which the two rails may be squeezed together when brought to the welding temperature. The thermit is contained in a crucible above the mould (Fig. 6), and is ignited in the usual way. When the reaction is complete, the crucible is tapped by lifting up an iron nail which closes the outlet at the

bottom, the head of the nail being protected from fusion by a layer of fire-sand, through which it passes when lifted. On coming into contact with the molten iron in the crucible the nail is instantly melted, and the charge descends into the mould. The quantity of the charge is so regulated that the molten iron does not rise above the hollow part of the rails, the top being covered by the liquid slag, which is hot enough to bring this part to the welding

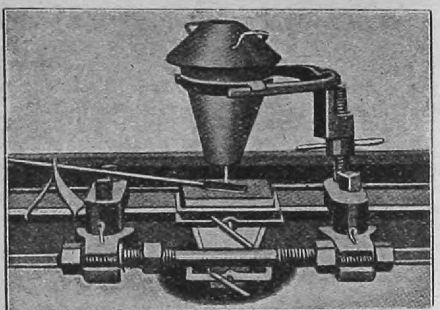

Fig. 6.—Outfit for Welding Rails by Thermit.

temperature. Pressure is now applied lengthwise, and the two rails become thoroughly united. On detaching the mould the alumina slag is broken away, and in the finished weld the under part of the rails and the hollow parts at the sides are united to the thermit iron, whilst the upper parts have been joined together by the pressure, as seen in Fig. 7. If thermit iron were attached to the top of the rails considerable labour would be required to smooth down the surface. In the few years immediately preceding the war, an average of 17,000 rail joints per annum were made in this manner in the United Kingdom. In effecting repairs of various kinds thermit welding has proved of great service. It has been successfully used in the case of large marine crank shafts, broken stern posts, etc., on ships, the quantity of thermit used being on occasion one ton or more. On locomotives it has been employed for the repair of cracked wheel centres, frames, horn blocks, etc.; and in general work for spur wheels, broken castings, and other purposes. Whenever possible, the broken part is preheated to a red heat before placing the mould in position and running in the thermit iron, it being thus ensured that the metal in the region of the crack shall become thoroughly fluid, and mingle with the thermit iron. In repairing breaks in cast-iron, 40 to 50 per cent. of steel punchings are added to the thermit, so as to lower the temperature of the reaction; and 15 to 20 per cent. may be added when welding mild steel if excessive heating is feared. Tests of thermit welds show that the union is complete, and that the strength of the joint is equal to that of the surrounding parts. The value of thermit for effecting repairs has been fully established during the present war, it having been used for emergency work of all kinds.

The thermit reaction has also been applied to the production of pure metals, and has proved of great value in cases where it is necessary to secure a product free from carbon. In the manufacture of special classes of steel in which manganese or chromium is used, it is desirable that these elements should be free from carbon, in order that the final carbon content may be regulated to any desired amount in the finished product. As prepared by furnace methods these metals always contain carbon to a greater or less extent, and hence for high-class steel the carbon-free metals produced by the thermit method are preferable—although more costly. The procedure is simply to mix the oxide of the metal to be extracted with the correct portion of aluminium, and to commence the reaction as in the case of iron thermit. When preparing 2 or 3 cwt. of metal only a portion of the charge is placed in the container at the commencement, and after ignition the remainder of the charge is added in portions until the container is full. The mass is then allowed to

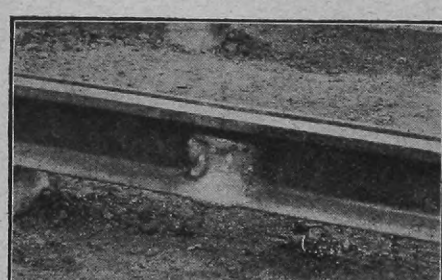

Fig. 7.—A Finished Thermit Weld on Tramway Rail.

cool, and is then removed and broken up to detach the metal from the alumina slag, the volume of which is three times that of the metal. Alloys may be prepared by using mixed oxides, and a large variety are made for industrial use. Amongst the metals and alloys so produced are chromium, manganese, cobalt, ferro-chromium, chromium-manganese, nickel-chromium, manganese-copper, and ferro-titanium, a total of thirty different products being on the market.

Before the war the thermit industry was in German hands, and it is a matter for congratulation that the present British proprietors have been able to reproduce practically all the compositions which previously were imported. This is an excellent example of the value of research in applied science.

No satisfactory use has yet been found for the alumina slag resulting from thermit reactions, although attempts have been made to utilise it for the manufacture of refractory crucibles, and for abrasive purposes. The material has qualities which fit it for either of these uses, but as it is inferior in these respects to other substances on the market, alumina slag cannot be profitably used at present.

The use of thermit in warfare is familiar to most people, as many incendiary bombs depend upon it for their action. The striking of the bomb brings about the ignition of the thermit, which, owing to the high temperature produced, is well adapted to the purpose intended. There are, in addition, a number of other military uses of thermit, the details of which cannot be given at the present juncture.

Metallic calcium has been used by F. M. Perkin and others instead of aluminium, and produces a similar thermit reaction. Commercially, calcium thermit has been restricted to the production of calcium silicide and a few other substances.

The Electric Furnace.

The employment of electric heating for large-scale operations has extended rapidly during recent years, particularly in localities where water-power is abundant, and electricity can be produced cheaply. Thus in Norway important industries have arisen, such as the manufacture of calcium carbide and the fixation of atmospheric nitrogen; and similarly the harnessing of Niagara has given rise to the production of artificial graphite, carborundum, and alundum by means of the electric furnace. In addition to the manufacture of substances only producible at high temperatures, the electric furnace has in many cases become a direct rival to fuel. In Sweden, for example, the output of electric furnaces in 1915 was as under :—

	Metric tons.
Iron	33,075
Ferro-silicon	11,819
Manganese ferro-silicon . .	2,328
Ferro-manganese	957
Zinc	8,588

Since then large developments have taken place, the most recent project being the erection of iron-smelting works at Porjus capable ultimately of an output of 100,000 tons per annum. Even in countries where fuel is cheap the use of electric furnaces is extending, as the superior value of the product often more than compensates for the extra cost of the heat generated. The rapid progress of the electric smelting furnace is indicated by the fact that in 1904 there were only four such furnaces in Europe and America, whereas the number in 1913 had arisen to 114; and so great has been the development during the war that more than seventy are now in use at Sheffield alone, in addition to others in various parts of England.

Electric furnaces may be divided into two types, the arc and the resistance. In the former an arc is struck between two or more carbon electrodes, and the material to be treated passed between the electrodes, or placed below them on the hearth of the furnace. In the resistance type, the current is conveyed by granular coke or other form of carbon, which is thereby raised to an extremely high temperature. A third variety, not now used to any great extent, is the induction furnace, in which the charge of material, which must be a conductor, takes the place of the secondary winding of a transformer, and is heated by the induced current which passes through it. The forms taken by electric furnaces in practice vary greatly according to the nature of the product, and detailed descriptions will be reserved for consideration in connexion with the materials dealt with later.

The temperature attainable in the electric furnace is only restricted by the vapourising point of the substance operated on, which in the case of carbon is 3700° C., and for iron, 2450° C. It is not necessary, however, to reach these temperatures unless desired, as the current may be regulated for any lower degree in most operations. Alternating current, either single or three-phase, is generally used, owing to the easy regulation of voltage by means of transformers, and the absence of electrolysis. In cases where the action is electrolytic, as in the reduction of aluminium, direct current is necessary and therefore employed.

Electric Steel-smelting.

The rapid increase in the output of electric steel is due to several causes, chief amongst which are (1) the superior properties of the

product; (2) the possibility of producing steels according to a given formula without difficulty; (3) the greatly reduced loss from oxidation of light steel scrap fed into the mixture; and (4) which applies specially to Britain, the possibility of obtaining a cheap supply of energy in certain localities. When all these factors are taken into account, high-grade steel can be produced more economically by the electric furnace than by the aid of fuel.

One of the earliest forms of steel-smelting furnace was due to Héroult, who employed three-phase current. Three carbon electrodes, spaced 120° apart, were placed above the charge, and arcs struck between them, the heat from which melted the metal below. Owing to the rotating field produced by the three phases, the molten metal rotated horizontally, causing a certain amount of mixing of the charge, and the product was satisfactory. A more modern type of furnace, the Greaves-Etchells, is shown in Fig. 8. In this two upper electrodes are used, connected to two phases of the three-phase supply, the third phase being joined to an electrode beneath the hearth. This arrangement results in heating from below as well as above, and in consequence a circulation is set up in the molten metal which ensures a uniform composition throughout. The lining of the hearth is of dolomite; and special devices are used to keep the phase currents balanced. In the furnaces made by Electro-Metals, Limited, two-phase current is employed, produced by transformers from three-phase supply; a suitable means of balancing being provided, and the arrangement being such that the metal is heated from above and below, as in the Greaves-Etchells furnace.

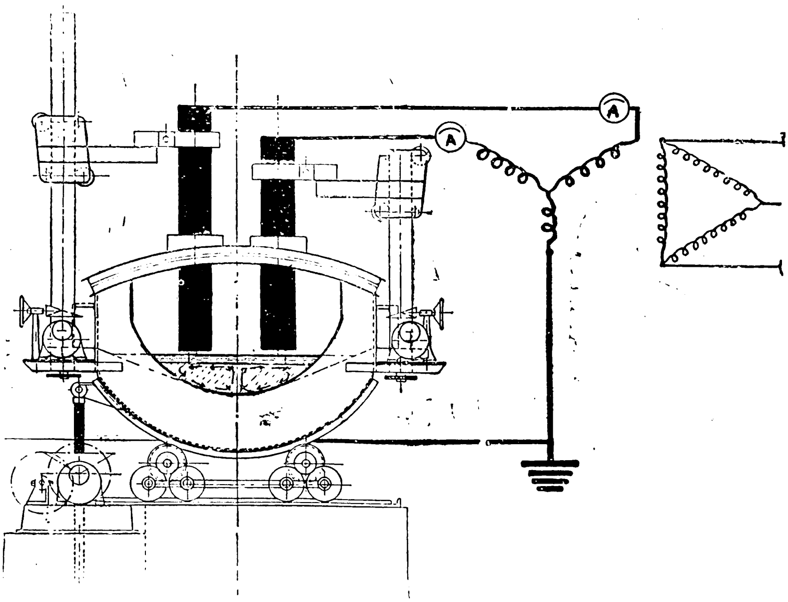

Fig. 8.—Greaves-Etchells Electric Steel Furnace.

The electric furnace has proved of great service in the manufacture of high-speed and special alloy steels, which it is capable of producing from cheap scrap and metal turnings, to which, after refining on the hearth of the furnace, the necessary portion of alloy is added. A product is then obtained of more uniform composition than that which results from melting in crucibles, and in addition it is possible to deal with larger quantities, meltings up to three tons of high-speed steel having proved successful. A further advantage of electric smelting is that steel castings of the best quality can be produced, which require no annealing, and can be easily machined. Such castings may be made from scrap and turnings, and owe their good qualities to the fact that the high temperature existing in the furnace renders the steel extremely fluid, which enables entangled slag and gases to rise to the surface. Furnaces of thirty tons' capacity have been constructed, and this is considered by some authorities to be the upper limit of economic size. One of the chief drawbacks at present is the rapid deterioration of the refractory lining; but this trouble will no doubt be overcome

by the production of durable refractories by electric furnace methods. In the event of one or more of the super-power stations proposed by the Coal Conservation Committee being erected near London, it is quite possible that the metropolis may become an important centre of the steel-refining industry.

In addition to steel, alloys such as ferro-silicon, ferro-chrome, and ferro-tungsten are manufactured in the electric furnace, being used subsequently for making alloy steel. Generally speaking, the alloys made in this way are not so pure as when produced by the "thermit" process, but are still sufficiently good for most purposes.

Fixation of Atmospheric Nitrogen.

The necessity of securing a source of nitrates to replace the supplies now obtained from South America, which sooner or later must become exhausted, has been recognised by all civilised nations, and the problem of oxidising atmospheric nitrogen on the large scale has been made the subject of investigation in most countries. Under peace conditions, the chief value of nitrates is for fertilising purposes; but during the present war immense quantities of nitric acid are needed for the manufacture of explosives. Several methods have been developed, some of which involve high-temperature reactions, and others (which depend upon the production of ammonia and its subsequent oxidation by catalytic means) in which only relatively low temperatures are employed. The former only will be dealt with as coming within the scope of the present lectures; but it may be stated that in all probability the low-temperature methods will prove the more economical.

Direct oxidation of the nitrogen in the atmosphere may be effected by the electric arc, and several types of furnace have been designed for the production of nitric acid by this means. When air is passed through the arc a quantity of nitric oxide is formed, which, in contact with cold air, combines with a further amount of oxygen to form nitrogen peroxide, NO_2. On dissolving this gas in water a mixture of nitric and nitrous acids is obtained, which may, if desired, be converted into salts by neutralisation. The efficiency of the process is restricted by the fact that if the nitric oxide exceed a certain concentration, it is decomposed by the arc; and Nernst has calculated that at 3000° C. the amount of NO in atmospheric air cannot exceed 5 per cent. for this reason. Hence in furnaces for this process provision must be made to remove the nitric oxide from the arc as rapidly as possible, and most early attempts failed owing to the absence of a satisfactory means of securing this end. The first successful apparatus was devised by Birkeland and Eyde in 1903, and consisted of a space lined with firebrick, into which copper electrodes, cooled by water, were inserted. The furnace was placed in the field of an electro-magnet, the lines of force of which passed at right angles to the plane of the furnace. On striking an arc between the electrodes by means of an alternating current, the arc was caused to rise and fall successively, being extinguished at the top and bottom of its path, and re-struck between the electrodes about 700 times per second. As a result of this continuous movement of the arc, the nitric oxide formed underwent the minimum of decomposition; and the air passing out of the furnace contained sufficient quantities of this gas to render the process commercially successful. A factory was erected at Nottoden, in Norway, working on these lines, which has remained in operation up to the present time; and numerous installations of the Birkeland-Eyde process have since been established in other countries. When properly worked, the process is capable of yielding 500 kilogrammes of nitric acid per kilowatt-year.

In the apparatus used by the Badische Anilin & Soda-Fabrik, a long arc is struck between electrodes inserted in the ends of a cylindrical tube, and pre-heated air is passed along the length of the arc for a certain distance, sufficient to ensure the production of the maximum amount of nitric oxide. A spiral motion is imparted to the entering air by suitable devices. This furnace has given good results, and has been used specially for the manufacture of sodium nitrite, which is used in the production of azo dyes. By allowing only a part of the NO to oxidise to NO_2, so that equal quantities of each are present in the treated air, sodium nitrite is formed directly by absorbing the mixed gases in soda. Many other forms of furnaces for the arc-fixation of atmospheric nitrogen have been devised, which, owing to considerations of time, cannot be dealt with in the present lecture.

Two other chief methods of nitrogen fixation, involving high-temperature processes, have been introduced; the Serpek process, in which aluminium nitride is first formed, and from which ammonia is obtained by treatment with

water; and the cyanamid process, in which nitrogen is passed over heated calcium carbide, yielding the compound $CaCN_2$, from which ammonia may be obtained by treatment with steam. In each case the ammonia produced may be converted by catalytic means into nitric acid. The Serpek process depends upon the reaction

$$Al_2O_3 + 3C + N_2 = 2AlN + 3CO$$

which is highly endothermic, and only commences at 1500° C. To ensure success the reacting temperature must be 1800° or 1900° C., and this is attained partly by fuel heating, and finally by an electric resistance furnace. Before the war, the Serpek process was being tested on a large scale in France, but it is not possible at present to state the final conclusions arrived at. The heat absorbed in the reaction is 213,220 kilo-calories or 248 kilowatt hours for 82 kilogrammes of aluminium nitride, or $\frac{1}{3}$ kw. year per ton.

Further reference will be made to cyanamid under the heading of calcium carbide.

Calcium Carbide.

When a mixture of carbon and lime is heated in an electric furnace, a reaction takes place which results in the formation of calcium carbide, according to the equation—

$$CaO + 3C = CaC_2 + CO.$$

The carbon is used in the form of coal or coke, and the purity of the carbide produced depends upon the quantity and nature of the ash in the coal or coke, and upon the foreign matter present in the lime. Anthracite coal, containing not more than 5 per cent. of ash, or a good coke of ash content not exceeding 6 per cent., should be used to produce a high-class carbide, the best qualities of both being obtained in South Wales. When carbide is used for making acetylene, the raw materials should be as free as possible from sulphur and phosphorus, as a part of these substances appears in the acetylene, and they are objectionable when the gas is used either for welding or lighting. A coal or coke containing not more than 1 per cent. of sulphur and ·04 per cent. of phosphorus, and a limestone in which the phosphorus is not more than ·01 cent., would be satisfactory in this respect. Of mineral impurities incidental to lime, magnesia to the extent of 1 per cent., silica 2 per cent., and traces of alumina may be permitted without detriment to the carbide produced.

The furnaces used are either of the single-phase type, in which the current is led through a vertical electrode to the mixture, passing out through an electrode at the bottom of the furnace; or three-phase, usually arranged with three vertical electrodes between which the current passes, and beneath each of which the carbide collects. Carbon electrodes are used, and the voltage employed in different cases varies between 100 and 30. Provision is made for tapping off the molten carbide, which is packed and sold under the rules of the British Acetylene Association. The pre-war consumption of carbide in this country was about 30,000 tons, of which all but about 2000 tons was imported. The small quantity made at home came from the works of the British Carbide Products, Ltd., at Thornhill, where power was obtained from the Yorkshire Power Company. The demand for carbide for various purposes has greatly increased during the war, and the works of the company named have now been removed to Clayton, near Manchester, where furnaces have been installed capable of turning out 15,000 tons per annum, power being taken from the Manchester Corporation. The cost of production is much greater than in Norway, where water-power is used, but this consideration is overborne under present conditions by the necessity of securing adequate quantities of carbide for welding, and for certain military purposes.

At first the use of carbide was restricted to the production of acetylene for lighting and welding, but during recent years two new applications have added greatly to its importance. One of these is the fixation of atmospheric nitrogen, and the other the synthetic production of alcohol and acetone. In the former process, nitrogen obtained from liquid air is passed over the heated carbide, forming cyanamid, $CaCN_2$. This substance may be applied directly to land as a fertiliser, in place of other nitrogenous manures, and is now extensively used for this purpose. When acted on with steam, cyanamid is decomposed, yielding ammonia, which may be converted into ammonium salts or oxidised to nitric acid by catalysts. Methods of producing alcohol by synthesis, using acetylene as the starting-point, have been devised, and may prove of great importance. It is stated that the quantity of carbide used in Germany for these secondary purposes rose from 8,000 tons in 1914 to 300,000 tons in 1917. It is not easy to predict the extent to which these processes will develop, under normal conditions, in competition with rival methods; but there appears to be good

reason to believe that the demand for carbide will continue for these purposes after the war. Whether the manufacture of carbide in Britain will become a large and profitable industry depends upon the success or otherwise of schemes for producing cheap electrical power.

Carborundum and Allied Substances.

The history of carborundum furnishes one of the romances of science, and shows how a small laboratory experiment may result in the establishment of a large and prosperous industry. Moissan, in his early experiments, observed the action of carbon on silicon, but did not develop his discovery. Working independently, Dr. E. G. Acheson, in America, found that, on subjecting coal and sand to a powerful electric current, crystals of an intensely hard material were formed. He produced a quantity of these crystals and had them tested for the grinding of gems, with such satisfactory results that the material was marketed, and sold to jewellers first at 40 cents per carat, and later at 20 cents, or £175,000 per ton. The production of four ounces per day exceeded the demand, and as a fresh outlet the substance, under the name of carborundum, was sold for valve grinding at £2 per pound. The demand grew, and to meet it furnaces using 135 E.H.P., and producing 45 tons per annum, were installed, the price being dropped to 2*s.* per pound. In 1894 the Carborundum Company entered into a contract with the Niagara Falls Power Company, to use 1000 E.H.P., and in 1895 production commenced at the new plant. The applications were extended by the production of abrasive wheels as a rival to emery, over which carborundum showed a marked superiority for most purposes. Later, papers and cloths coated with carborundum were produced, and as the result of continuous progress the output exceeded 5,000 tons per annum before the war, and has since greatly increased. Carborundum has now become an essential material in modern industrial practice, and has greatly simplified and shortened many operations.

The main reaction in the production of carborundum is shown by the equation:—

$$SiO_2 + 3C = SiC + 2CO.$$

Carborundum is therefore chemically silicon carbide. In the manufacture on the large scale, a mixture of sand, coke, and a quantity of common salt is placed in the electric furnace round a core of granular carbon, through which the current passes. The portion of the mixture adjacent to the core is converted into carborundum to a certain depth, beyond which a partial conversion only takes place, forming what is known as "fire-sand." The furnace is built of loose brickwork, and provided with vents for the carbon monoxide and vapours given off; and after cooling down the furnace is dismantled and the contents removed and separated. The mass of the carborundum consists of relatively small crystals, but frequently cavities are found filled with large, brilliant crystals, which are now a familiar sight in the windows of shops which deal in abrasive materials. The large crystals are not used in the manufacture of grindstones, but find an application in the hulling of rice, for ornamental signs, and for crystal detectors in wireless telegraphy. The finer crystalline mass forms the basis of carborundum abrasives. The chief sources of carborundum are the electric furnaces of the Carborundum Company at Niagara, and of the Norton Company, Chippawa, Ontario, the product of the latter company being designated by the trade name "Crystolon."

Silicon carbide as thus formed has a specific gravity of 3·12 to 3·20, and a wheel made of it weighs about 135 lb. per cubic foot. It cannot be fused, but if heated above 2250° C. decomposes. It is not acted on by pure oxygen below 1000° C., and is not attacked by boiling acids, even hydrofluoric. It is decomposed by fused alkalies, and is readily attacked by iron oxide, basic slag, and molten steel, which detracts from its use as a refractory. The most useful property of carborundum is its hardness, which approaches that of the diamond. The crystals have an irregular fracture, so that when broken in a grinding operation a sharp-cutting edge is always presented to the work. A grindstone made of it possesses a degree of toughness which fits it for the grinding of cast-iron, bronze, brass, copper, aluminium, marble, granite, slate, glass, and a number of other materials; but it is not sufficiently tough for successful use on steel, malleable iron, or materials of high tensile strength. In preparing the material for abrasive purposes, the mass taken from the furnace is broken up by crushers, and afterwards sifted through sieves of different mesh, producing grits of graded size, which are mixed with a bonding material and made into grindstones. Fine powders are also made for polishing purposes by subjecting the material which passes through the finest sieve to a process of settlement in water, the grading being decided by collecting the settled portion at definite intervals, ranging from one minute for the coarsest particles, and

100 minutes for the finest. Abrasive articles of carborundum are now manufactured in this country by the Carborundum Company, Ltd., at Manchester, the raw material being obtained from Niagara. Carborundum grindstones are now used in most engineering works, and in the small form are employed largely by dentists. In cutting stone mouldings, shaped grindstones are used against which the stone is pressed, the finished shape being rapidly imparted. In the form of slabs, carborundum is used for facing flat stone-work, etc.; and in the form of powder for lapping hard steel, and for polishing metals and stone. Carborundum cloth and paper are used largely for metalwork and woodwork in place of emery cloth or sand paper. Taken all round, carborundum is one of the most useful abrasives available, and merits the wide application it has received.

Carborundum sand, the outer zone product, is used for lining brass furnaces, silicate of soda being used as bond. It is also used, mixed with fireclay, as a furnace lining, as a moulding sand for aluminium, and for many refractory purposes.

A number of investigations have been made—chiefly in America—of the reactions of the carborundum furnace, and it has been found possible to produce several useful materials by modifying the working conditions. The reaction between silica and carbon commences at 1550° C., and the first product is a solid solution of SiC and SiO_2, known as "siloxicon." As the temperature rises, vapours of silicon are produced, which penetrate the carborundum already formed, and which play a part in the progress of the reaction. By raising the temperature to 1820° C., the complete conversion of the materials into silicon carbide may be effected, but the product is amorphous, and is known as "silfrax." At temperatures between 1820° and 2220° C. the crystalline variety, or ordinary carborundum, is produced; but if the temperature be still further increased decomposition occurs. In a normal run of a carborundum furnace the outer zones do not attain the highest temperature, and consist therefore of the partly-formed material, and contain siloxicon and silfrax. Both these bodies are good refractories; and silfrax has been made, by restricting the temperature as described, for manufacture into crucibles, pyrometer sheaths, and chemical ware, its resistance to acids being identical with that of carborundum. A number of other reactions occur in the carborundum furnace, one of which results in the formation of a material known as "fibrox," which appears as excessively fine threads, the diameter of which is only 0·6 micron, or just larger than the wave-length of yellow light. This remarkable material may be produced in greater quantity by the action of carbon dioxide on silicon, and is only a casual product of the carborundum furnace. A space of 1,000 cubic centimetres filled with fibrox packed by hand-pressure, contains only 2·5 to 3 grams of the solid; and hence it may be inferred that fibrox is an excellent heat insulator, as is fully borne out by experiment.

By using a lesser quantity of carbon, the element silicon may be prepared in large quantities in the electric furnace, the reaction being—

$$SiO_2 + 2C = Si + 2CO.$$

The formation of silicon was first noted in the carborundum furnace, in which small quantities may be found; and this led to the production of silicon as the primary substance, when desired, by reducing the proportion of carbon as shown. The element silicon thus became available in bulk, whereas previously it was more or less a laboratory curiosity. Silicon does not oxidise below 1200° C., and is useful as a resistance material for electricity, particularly when strong currents are used which make the resistor very hot. Its specific resistance is about three times that of carbon. When silicon powder is mixed with chlorate of potash, a powerful explosive is produced; and when mixed with some metallic oxides and ignited, a "thermit" reaction ensues, resulting in the reduction of the metal. This reaction, however, is weaker than when aluminium is used, the heat of formation of 1 molecule of SiO_2 being only 219,000 calories, compared with 393,000 for Al_2O_3. There is little doubt that silicon will find applications in many directions in the future, one promising line being the preparation of hydrogen on the large scale by acting on silicon with caustic soda.

[Samples of thermit welds and of pure metals prepared by the thermit reaction were exhibited by Thermit, Ltd., and specimens of carborundum abrasive appliances by the Carborundum Company, Ltd.]

OIL-YIELDING PLANTS IN INDO-CHINA.

M. Brenier, Director of the Chamber of Commerce of Marseilles, gives, in *Comptes Rendus des Séances de l'Académie d'Agriculture de France*, some interesting facts concerning the resources of Indo-China in oil-yielding plants.

From 1912 Germany imported 1,425,000 tons of oil-yielding seeds, whereas France, the chief importing country up to that date, only imported 1,219,000 tons in 1913, and England about one million tons. As the English oil mills increased their producing capacity by 25 per cent., importations into England rose to 1,700,000 tons in 1915, but fell in 1916 to 1,400,000 tons, still exceeding the French figures.

France has the greatest interest in finding in her colonies the raw materials necessary to the fat industry. From this point of view Indo-China offers resources of the greatest importance.

Among the plants grown M. Brenier mentions particularly the Chinese tallow tree (*Stillingia sebigera*), which grows in the north of Tonkin and supplies white vegetable tallow, and the wild varnish (*Rhus succedanea*), a lac tree cultivated in the Province of Putho, the seeds of which supply Japan with green vegetable tallow.

Amongst other trees capable of supplying raw material, though in small quantities only, may be mentioned: Mast-wood (*Calophyllum Inophyllum*), in Cochin-China; a species of Mahua (*Bassia* sp.) in North Annam; *Camellia drupifera*, in the same district and in Tonkin; *Garcinia tonkinensis*, a native of Indo-China; soap-nut (*Sapindus Mukerosei*).

"Abrasin" (*Aleurites montana* or *A. Jordii*) should also be mentioned on account of the drying properties of its oil, which is superior to that of linseed, and because it is well adapted to village plantations in Central Tonkin.

The most interesting cultivated plants are—the cotton plant, hevea, soya bean, castor oil-plant, sesame, peanut, and coconut.

The cotton plant is cultivated in Indo-China in the north of Annam and in the Province of Thanh Hoa, where the large population supplies abundant labour for the harvest. Large cotton-fields are situated at Cambodge, on the banks of the Kompong-Cham. Their produce, from 3,000 to 5,000 tons according to the year, is bought by Japan. The Lancashire mills use 500,000 bales of this cotton, which the British have introduced into India. Cotton seeds have a high value in oil yield, and when this plant is cultivated more largely at Cambodge French buyers will be able to obtain large quantities of seed.

Five million hevea plants have been put down. The Imperial Institute pointed out long ago the value of the drying properties of hevea-seed oil. The ratio of the yield in kernels to seed is 50 per cent., and the yield of oil from the kernels is 42 per cent. (laboratory tests). This produce is a secondary resource which should not be ignored.

The oil yield of the Cambodge soya bean is superior to that of Manchurian soya, although it does not exceed 18 per cent. The castor-oil plant is of great interest in Indo-China. It is chiefly cultivated in Tonkin, and is exported to Hong Kong and the Far East. In laboratory experiments, 42 per cent. of oil has been obtained, but by the European methods used in the few small mills of the country only 35 per cent. is obtained. Castor oil is much in demand at the present time as a lubricant. The value of the cakes used as manure is well known. Analysis made at Saigon showed the presence of 4·75 per cent. of nitrogen and 2·25 per cent. of potassium.

Sesame is cultivated in Tonkin and Annam, and might well be grown in Cambodge and Cochin-China. It gives a very high oil yield, sometimes as much as 50 per cent. Analysis proves the oil yield of Tonkin sesame to be very remarkable. The pure cultivation of sesame in Tonkin gives a yield of 9¼ cwt. per acre, whereas in British India, where enormous quantities of sesame are exported, the yield from mixed cultivation is only from 4 cwt. to 4½ cwt. per acre. From 1899 to 1903 the maximum annual importation of sesame into France rose to 139,000 tons.

In good years as much as 420,000 tons of peanuts are imported into Marseilles; this represents about a third of the French imports of fat. Although Senegal supplies 200,000 tons, this quantity does not nearly meet the commercial demands, and its further cultivation in other colonies is therefore most desirable. Light soil, indispensable to the cultivation of the peanut, is found in Tonkin, Central Annam, Cochin-China, and Cambodge. Experiments show the ratio of the shell to the whole seed to be equal to that of the best African varieties (32 to 24 per cent.). As the Annamite methods of cultivation are superior to those of the negroes, a higher yield is obtained than in West Africa. In Africa the yield is from 20 to 29 cwt., whereas in Indo-China it is as high as 39 cwt., or, in good soil, even 49 cwt. M. Brenier imported from Java a peanut which is very easily gathered on account of the grouping of the pods round the neck. This variety does very well in Indo-China, but appears to give a lower yield in oil than the ordinary peanut.

The coconut tree covers more than 24,711 acres. It is grown chiefly along the Annam coast, which, being subject to typhoons, is not the most favourable situation. The coconut grows along the south coast, and also in the interior of Cochin-China, where its cultivation is localised in the towns of Mytho and Bentre. The coast of the Gulf of Siam, outside the typhoon zone, appears to be the most favourable district for cultivating coconuts. The natives plant the trees much too close together, so that in Annam the yield of one tree does not exceed 23 to 25 nuts, whereas in plantations owned by Europeans, where the trees are farther apart, as many as 50 to 75 are obtained. The yield in copra and in "coir" (fibre obtained from the mesocarp) of the coconut trees of Indo-China competes closely with that of coconut trees in Malaya, Ceylon, the Indian Archipelago, and the Antilles. As desiccation causes a loss of 50 per cent., distinction must be made between the green kernel and the copra in estimating the yields. If copra is valued at £2 per 220 lb. (its actual value is

double that), the gross revenue from an average of 50 nuts per tree may be calculated at £10 per acre. If an average of 70 nuts per tree is taken, the revenue will be £14. The coconut tree bears fruit for fifty years. In the Malay Peninsula one acre of a European plantation is valued at about £25.

INDUSTRIES AFTER THE WAR.

In 1916 the Board of Trade appointed four Departmental Committees to consider respectively the position of the iron and steel, engineering, electrical, and textile trades after the war, especially in relation to international competition and to report what measures, if any, are necessary or desirable in order to safeguard that position. The chairmen of the several committees were: *Iron and Steel*—Mr. G. Scoby-Smith; *Engineering*—Sir Clarendon Golding Hyde; *Electrical*—the Hon. Sir Charles A. Parsons, K.C.B., F.R.S.; *Textile*—Sir Henry Birchenough, K.C.M.G. All the committees finished their work by the middle of the following year, but their reports were not presented to Parliament until towards the close of last Session. They have since been issued to the public.

I.—Iron and Steel.

The Iron and Steel Trades Committee say that the problem of which they have attempted to reach a solution is to give the nation industrial resources which in time of peace shall preserve the prosperity of Great Britain, and in time of war give her full command of resources adequate to the defence and safe-keeping of the Empire. The committee specially refer to the rapid development of these two industries, which they describe as one of the most striking features of the economic history of the nineteenth century, and to the revolution caused by the discovery of the Thomas (Basic Bessemer) process. It was only in or about 1880, when the Thomas process was applied to the open-hearth furnace, that basic steel attained comparative equality with acid steel, and not until ten years later that the Admiralty and Lloyd's permitted the former to be used in shipbuilding. The manufacture of steel in the electric furnace is still in its infancy, but the process is gradually extending for the manufacture of high-grade steel and for the production of castings of special quality, and there is every reason to anticipate that steel so produced from domestic raw materials will, to a great extent, replace the steel formerly manufactured from imported Swedish iron and steel in the specialised manufactures of the country. While as regards the ironfoundry industry there have been no "epoch-making discoveries," there is a record of steady progress in foundry practice and of improvement in the quality of the product as well as an advance in the scientific education of those engaged in the industry.

The scope of the inquiry being very wide, the committee treated the numerous subjects separately, and from time to time made interim reports to the President of the Board of Trade. These are reproduced in the general report, the names of the signatories, with or without reservation, being appended to each. The summary of recommendations is grouped under various headings. Altogether there are sixty-one recommendations. The first six deal with commercial reconstruction, and are as follows: (1) That all imports of manufactured or semi-manufactured products of iron and steel from present enemy countries be prohibited during the period of reconstruction; (2) that all ores and minerals necessary for the manufacture of iron and steel be admitted free, and all other materials necessary for the manufacture of iron and steel be admitted only in their natural or unworked state; (3) that no raw materials be sent to present enemy countries from British Dominions or Colonies, or from mineral or other resources under British control; (4) that British ships shall not carry raw materials or manufactured iron and steel from neutral ports to ports in present enemy countries or to neutral ports for ultimate despatch to enemy countries; (5) that careful Government consideration be given to the question as to whether the ships of present enemy countries shall be allowed to carry goods to or from ports in the British Empire, or to coal at any coaling station in the British Empire; (6) that licences be granted in cases where national interests demand the relaxation of the regulations recommended above, and that a fully representative committee of the iron and steel industries be appointed to regulate the issue of such licences where they directly affect the industries.

The other recommendations include the following: That an organisation be formed comprising users of iron ore, and others interested in and essential to the conduct of the trade, to undertake the import and distribution of foreign ores in Great Britain and acquire interests in ore properties abroad, and that such organisation should receive Government financial assistance if necessary; that no mining concessions within the Empire be granted to any alien individual or company without Government sanction, and that the Dominions be urged to adopt a similar policy; that an adequate economic survey be made of the natural resources of Great Britain and other parts of the Empire; that iron and steel manufacturers associate themselves for the purposes of export trade, and form common selling organisations by the extension and consolidation of associations which already exist; that an organisation—co-operative in character—be formed among British manufacturers for the purpose of obtaining adequate supplies of suitable iron ore; that a national selling organisation be formed for the purpose of marketing British iron and steel products in an efficient and economical manner, and that British iron and steel manufacturers be urged to form combinations for the purpose of laying down large and well-designed new units for cheap production upon modern lines.

Recommendations respecting labour relations, protection, royalties and wayleaves, means of transport, technical education, etc., follow.

Finally, general subsidiary questions are dealt with, and in this connection the committee recommend, *inter alia*, that where permission is given by H.M. Government for the raising of loans in the United Kingdom this permission be conditional upon the purchase of as much of the material required as possible in the United Kingdom, and that all purchases of iron or steel made by or for Government Departments, public bodies, railways, etc., within the United Kingdom shall be of British manufacture.

SYRUP OF GRAPES AS A SUBSTITUTE FOR SUGAR.

The great scarcity of sugar in the district of Turin, as well as in the entire Kingdom of Italy, and the Government prohibition of its use in wine-making processes, has effectually drawn attention, writes the United States Consul at Turin, to the sweetening methods which were employed during the economic crisis of 1790–1800, when it was found that syrup of grapes furnished a fairly satisfactory solution of the problem. The matter perhaps is of equal importance at present.

The experiments carried out at the period mentioned, although of great benefit, did not meet with all the success desired, on account of imperfect elimination of acids and the unpalatable character that the process of extraction imparted to the syrup. Although it is now recognised that syrup of grapes cannot take the place of sugar for general purposes, it is an excellent sweetening for jam, marmalade, etc., increasing their nutritive value.

For the extraction of the syrup of grapes it is of the utmost importance to use well-matured fruit, and alcoholic fermentation must not occur during the process. As it is difficult to ensure such conditions with the liquid in a state of repose, and as it is desirable to eliminate all solid particles and albuminous and pectic substances, it is necessary to use centrifugal force, by means of which 75 per cent. of the deleterious substances can be eliminated. It is also important to avoid any undue action of the press, which would tend to enrich the liquid at the expense of the extracted substances. A natural flow of juice should be sought, the liquid basis being contained in a receptacle furnished with a false perforated bottom. The liquid that issues from the channel of the apparatus is very sweet, and comes from the surface.

This operation must be well regulated, so that the action is effective both as to quality and quantity of the product. Any liquid which remains in the receptacle after the conclusion of the process of extraction may be fermented separately. The issuing liquor feeds the centrifugal machine continuously. Should the output of the latter diminish, the incoming flow of liquid should be arrested and the plate cleaned; in a few minutes the machine will again be ready to work. The liquid so obtained is poor in fermenting elements, and in order to ensure its preservation for several months, from 100 to 150 grammes of sulphate of potash per 100 hectolitres of liquid may be added; or the direct system of sulphurisation may be adopted, using sulphuric gas obtained from the combustion of sulphur. The latter method is considered to be most advantageous—at least, under present conditions, in view of the high price of potash. This process costs only about 1*d*. per hectolitre. By repeated trials it has been perfected, and apparatus has been brought out which avoids the necessity of the use of potash in wine-making processes.

PETITGRAIN OIL INDUSTRY OF PARAGUAY.

The chief article of direct export from Paraguay to the United States is oil of petitgrain, an extract obtained from the bitter orange leaves that are found abundantly in Paraguay. Exports of petitgrain oil invoiced at the American Consulate at Asuncion, writes the United States Consul, for exportation to the United States amounted to 23,040 lbs., valued at about £7,000, in 1915, and to 33,680 lbs., valued at about £12,000, in 1916. Previous to the war France was the principal market for the exports from Paraguay.

Oil of petitgrain is used as the basis of perfumes and perfumed toilet soaps. It requires 500 lbs. to 600 lbs. of leaves to produce a quart of the extract. The oil is extracted by packing the leaves into a barrel-like receptacle with perforations in the bottom, through which steam is passed. A pipe leading from the top of the receptacle conducts the steam, which also contains the extract in vapour form, to a condenser where the mixture is cooled and the oil appears on the top ready to be drained off. The product in this form, which is considered ready for market by some producers, has a distinctly oily odour. Some of the more important producers have a secret process of distillation that further refines the extract, leaving it with a perfume like that of Florida water. When tested by a densimeter, the specific gravity of the distilled extract is found to be about 28 or 30.

NOTES ON BOOKS.

THE BERNERS ESTATE. By John Slater. Unwin Bros. 1918.

This interesting "short history" of the estate to which the author is surveyor offers an example which the owners, or officials, of the other great London estates would do well to follow. The Bedford estate, for instance, though its history does not run nearly as far back as that of the property with which Mr. Slater is associated, occupies an area even richer in historical traditions, and it is known to possess a complete and carefully compiled record of all the changes and

alterations in the property since it first came into the possession of an ancestor of its present owner. There must exist, in the private records of the London estates, where these have, as no doubt they have, in most cases for legal purposes, been carefully preserved, a large amount of detailed information, which would be of value, if available, to students of London history. It is to be hoped, therefore, that Mr. Slater's little book will not long be the only one of its sort, and it may also be hoped that its successors may be as well and as carefully compiled, for it is full of interesting material.

Of all the London estates there is, it is understood, no other which can compete with the Berners estate as regards antiquity of record. The estate was purchased by Josias Berners in 1654, but the documents in the owner's possession enable its history to be traced back to 1546 "when it formed part of the old Leper Hospital of St. Giles, which probably acquired it by private bequest or gift in the reign of Edward I." (1272–1307), so that the history of the estate, so far as it can be said to have any history in these early days, may be said to be known from the end of the thirteenth century. After the dissolution of the hospital, the ground now forming the estate was granted by Henry VIII. to John Dudley, afterwards the Duke of Northumberland, who was beheaded for his attempt to put Lady Jane Grey on the throne. He sold it to Wymond Carew in 1596, and the deed of sale, with all the subsequent deeds effecting transfers of the property, is now in the keeping of the office of the estate. The record therefore is continuous and complete for six centuries. An interesting description is given by Mr. Slater of the surroundings of the property when it was bought by Josias Berners in 1654. It was then a country farm, with fields running down to what was then Tyburn Road, and is now Oxford Street, a country road with no houses upon it except a few taverns, the resort of footpads and other bad characters. Further west was a bridge over the Tyburn, then one of the chief sources of London water-supply, with Tyburn Tree a little further along, either, as Mr. Slater says, near where the Marble Arch now stands, or on the other side of the road. The estate itself, whatever alterations it has undergone, covers the same area in 1918 that it covered in 1654. Its Oxford Street frontage, about 320 yards, extends from Wells Street to Perry's Place, and the property runs back to the Middlesex Hospital. It also comprises a long strip along the southern side of Cleveland Street. The modern development of the estate was started about 1750, when the existing streets were laid out, Berners Street itself dating from 1763. At the end of the eighteenth century and the beginning of the nineteenth it was a fashionable residential district, where many well-known persons lived. Some of these are mentioned by Mr. Slater, and to those whose names he records may be added, on the authority of the late Mr. H. B. Wheatley, some other well-known Berners Street residents. Opie, the celebrated artist, and J. Lonsdale, the portrait painter, both lived at No. 8; Sir Robert Smirke, R.A., the architect, No. 13; Henry Bone, R.A., painter in enamel, No. 15, where he died in 1834; Dr. Robert Gooch, the well-known physician, No. 19; W. Shield, the composer, No. 16; James Bartleman, bass singer, No. 45; and Richard Warrington, actor, No. 29.

It may also be mentioned that Sir Thomas Chambers himself built his house, No. 53, and that it was for many years the home of the Medical and Chirurgical Society. Theodore Hook's famous Berners Street hoax was perhaps considered too trivial an affair to deserve record in a serious history, though it formed the subject of an article in the *Quarterly Review*. James Barry, it may be added, not only lived in Castle Street, but he died there.

GENERAL NOTES.

Big Harbour Scheme for Naples.—The largest dock in the Mediterranean is to be constructed near Naples. According to the *Giornale d'Italia* the decree has been signed conceding to that city the right of carrying on the necessary constructional works in the harbour of Baia. Among the minor undertakings will be the transformation of Lake Averno into a marine basin, with a large industrial zone adjoining the construction of an outer harbour in the Gulf of Baia and of a communicating canal between this harbour and the lake, with a quay provided with all the latest appliances. The total cost is not to exceed L.50 mill., to which the State will contribute L.22 mill. in fifty annual instalments. All the works are to be commenced at latest within six months after the declaration of peace, and to be finished within six years. After sixty years all the works are to become the property of the State without further payment.

The Oldest British Industry.—It appears that one effect of the war has been to put an end to what is certainly the oldest British industry, that of the flint "knappers" of Brandon in Suffolk. There is every reason to believe that it has been carried on from neolithic times, and how many thousands of years this was before the Roman invasion of Britain, not even geologists are in a position to decide. To say that it has been carried on continuously would be too much. It may have been interrupted by prehistoric warfare, though, as in those days it must have been the principal munitions factory for the locality, such interruptions were improbable. It is the lack of labour, not the absence of demand for gun-flints and "strike-a-lights," that has stopped work at Brandon. There was still, before the war, a trade in gun-flints to Africa and South America. Till the work was stopped it was carried on precisely in the same way as in prehistoric times. The flints were quarried by sinking short shafts, and when the supply from each little shaft was

exhausted, it was filled up, and a new one started. No mechanical power, not even a windlass, was used in bringing the flints "to bank." The men carried them on their heads, ascending by means of steps cut in the sides of the shaft, just as their prehistoric predecessors did. The splitting and chipping of the flints was effected in the ancient methods, indeed the devices of the modern knappers have thrown a good deal of light on the methods by which the old flint implements were made. Fortunately before the industry became extinct, it found an admirable historian in Mr. S. B. T. Skertchley, who described it fully and with exhaustive detail in one of the *Memoirs of the Geological Survey* in 1879. Whether the industry will ever be renewed remains to be seen. Probably it will be difficult to recover the traditional skill handed down in the families of knappers, and the skill required is very considerable. Once lost, it is not likely to be recovered.

War-time Boots for Civilians.—In an article in the *Board of Trade Journal* on "The Control of Leather," reference is made to the steps that were taken in view of the possibility of a serious shortage of civilian footwear, especially for the poorer classes. It was decided that the War Office should intervene to the extent of controlling production by requiring manufacturers to produce certain quantities of boots for the general working-class population, and that the prices of these boots to the public should have some definite relationship to the cost of production. Sixteen committees were appointed throughout the country, and they were asked to select a range of the boots that could most economically be made in their respective areas. Over 200 samples were submitted, but since the admission of so great a variety would have rendered standardisation ineffective, the number was reduced, and it now stands at about 80. The prices finally fixed allow a profit of 5 per cent. to the average manufacturer, and the retail trade agreed to handle the boots at an addition of 33⅓ per cent. on the manufacturers' prices. If the services of a factor are employed his remuneration comes out of the 33⅓ per cent. Manufacturers have been instructed to devote one third of their non-military capacity to the production of war-time boots, and this has priority over all other work except Government contracts.

Transport Facilities.—The House of Commons, on August 6th, ordered that a Select Committee be appointed for the purpose of considering what steps, if any, it is desirable to take to develop and improve the internal facilities for transport within the United Kingdom; to secure effective supervision and co-ordination; and to ensure that such developments and improvements shall be adequate and suitable to meet the national requirements. The Committee, which numbers fifteen, has been granted power to send for persons, papers and records, and to appoint from outside such additional persons as it may think fit to serve on any sub-committee it may decide to establish.

THE LIBRARY.

The following books have been presented to the Library since the last announcement. Except where otherwise stated they have been presented by the publishers:—

Aundh, The Chief of.—The Picture Ramayana. Bombay: British India Press, 1916.

Bayley, Thomas.—A Pocket Book for Chemists. Eighth Edition. London: E. & F. N. Spon, Ltd., 1917.

Bell, A. H., B.Sc.—Algebra—theoretical and applied. London: Blackie & Son, Ltd., 1917.

Boone, William T., B.A., B.Sc.—A Complete Course of Volumetric Analysis. London: Blackie & Son, Ltd., 1918.

Borden, Sir Robert, G.C.M.G.—The War and the Future. London: Hodder & Stoughton, 1917.

Brown, George E.—British Journal Photographic Almanac, 1918. London: Henry Greenwood & Co., Ltd., 1918.

Burnet, John.—Higher Education and the War. London: Macmillan & Co., Ltd., 1917.

Butler, G. Montague.—A Pocket Handbook of Minerals. Second Edition. London: Chapman & Hall, Ltd.

Carey, Alfred E., M.Inst. C.E., and F. W. Oliver, F.R.S.—Tidal Lands: a Study of Shore Problems. London: Blackie & Son, Ltd., 1918.

Casson, Herbert N.—Human Nature. London: The Efficiency Magazine, 1918.

Caven, R. M., D.Sc.—A Short System of Qualitative Analysis. London: Blackie & Sons, Ltd., 1917.

Clapham, Charles B., B.Sc.—Arithmetic for Engineers. London: Chapman & Hall, Ltd., 1916.

Climates and Baths of Great Britain.—2 Vols. London: Macmillan & Co., Ltd., 1895 & 1902. Presented by the Royal Medical and Chirurgical Society of London.

Dales, Benton, Ph.D., and Oscar Leonard Barnebey, Ph.D.—Elementary Qualitative Analysis. London: Chapman & Hall, Ltd., 1916.

Davison, T. Raffles.—Port Sunlight. London: B. T. Batsford, Ltd., 1916.

de Villamil, Lieut.-Col. R., R.E.—Resistance of Air. London: E. & F. N. Spon, Ltd., 1917.

Dover, A. T.—Electric Traction. London: Whittaker & Co., 1917.

Ellis, E. T.—Jottings of a Gentleman Gardener. London: L. Reeve & Co., 1917.

Gayley, Charles Mills, Litt.D., LL.D.—Shakespeare and the Founders of Liberty in America. New York. The Macmillan Co., 1917.

Goulding, Ernest, D.Sc.—Cotton and other Vegetable Fibres. London: John Murray, 1917.

Gregory, R. A.—Discovery, or the Spirit and Service of Science. London: Macmillan & Co., Ltd., 1916.

Grillo, Ernesto, D.Litt., LL.D., D.C.L.—1. Selections from the Italian Poets.—2. Selections from the Italian Prose Writers. London: Blackie & Son, Ltd., 1917.

Gupte, Rai Bahadur, B.A.—Hindu Holidays and Ceremonials. Calcutta: Thacker Spink & Co., 1916. Presented by the Author.

Holdich, Col. Sir Thomas H., K.C.M.G., K.C.I.E., C.B.—Boundaries in Europe and the Near East. London: Macmillan & Co., Ltd., 1918. Presented by the Author.

"Ironicus"—Evolution or Revolution. London: The Cursitor Publishing Co., 1918.

Jones, Ernest, M.Sc., and J. J. Griffith, B.Sc.—Chemistry for Rural Schools. London: Blackie & Son, Ltd., 1916.

Kitson, Arthur.—1. A Fraudulent Standard.—2. Trade Fallacies. London: P. S. King & Son, Ltd., 1917.

Knight, A. Charles.—Cordwainer Ward in the City of London. London: George Allen & Unwin, Ltd., 1917.

Maclean, Magnus, M.A., D.Sc.—Electrical Laboratory Course. London: Blackie & Son, 1916.

Matthews, Sir A. H. H.—Fifty Years of Agricultural Politics. London: P. S. King & Son, Ltd., 1915. Presented by the Author.

Meares, J. W.—Electrical Engineering Practice. London: E. & F. N. Spon, Ltd., 1917.

Mitchell, C. Ainsworth, B.A., F.I.C.—Edible Oils and Fats. London: Longmans, Green & Co., 1918.

Murdoch, Joseph, Ph.D.—Microscopical Determination of the Opaque Minerals. London: Chapman & Hall, Ltd., 1916.

Nickel.—Report of the Royal Ontario Nickel Commission. Toronto: A. T. Wilgress, 1917.

Osborne, R. S.—Commercial Calculations. London: Effingham Wilson, 1917.

Peddie, Robert A.—An Outline of the History of Printing. London: Grafton & Co., 1917. Presented by the Author.

Pennell, Joseph.—Pictures of War Work in America. Philadelphia: J. B. Lippincott Co., 1918.

Pilcher, R. B., & F. Butler-Jones, B.A.—What Industry Owes to Chemical Science. London: Constable & Co., Ltd., 1918.

Plimmer, R. H. A., D.Sc.—1. The Chemical Constitution of the Proteins. Part I. Analysis. Third Edition. 1917.—2. Practical Organic and Bio-Chemistry. New Edition. London: Longmans, Green & Co., 1918.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2.

Registered as a Newspaper.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,433. VOL. LXVI.

FRIDAY, SEPTEMBER 6, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

HIGH TEMPERATURE PROCESSES AND PRODUCTS.

By Charles R. Darling, A.R.C.Sc.I., F.I.C.

Lecture III.—Delivered February 4th, 1918.

Alundum and Aloxite.

The fusion of the mineral bauxite, an impure form of oxide of aluminium, results in the production of a crystalline material inferior in hardness to carborundum, but superior in strength. In grinding steel, or materials of high tensile strength, an abrasive material is needed which will not break under the pressure which must be applied, and in such cases it is found that grindstones made from fused bauxite are quite satisfactory, whilst carborundum wears away too quickly owing to the breaking of the crystals. Fused bauxite is manufactured into grindstones by the Norton Company in America under the name of "Alundum," and a similar product is marketed by the Carborundum Company of Manchester, which is termed "Aloxite."

The fusion of bauxite is effected by mixing the mineral with coke, and placing the mixture in a furnace provided with a carbon bed. Two vertical carbon electrodes pass into the mixture, and the current is conducted, in the first instance, by the coke. Above 1600° C., however, the bauxite becomes a conductor, and improves in conductivity as the temperature rises, finally melting at about 2000° C. When the mass is fused, any reduced iron from the iron oxide in the bauxite sinks to the bottom, whilst any unburnt coke floats to the top; and after cooling the interior of the mass consists of crystalline alumina, containing a greater or less quantity of oxide of iron, according to the quality of bauxite used. The mass is broken up in crushers, and separated into grits of varying fineness by passing through sifters of different mesh. In making grindstones of any desired grade, the grit chosen is bonded either with shellac, rubber, silicate of soda, or, by firing, with a vitreous clay bond; the bond used being decided by the nature of the work to be performed by the stone. As an abrasive for steel, fused bauxite is unrivalled, and together with carborundum has made possible the introduction of grinding machinery which for many purposes is preferable to steel cutting-tools, producing a better finish in a shorter time. The speed of revolution of the stone, in the average case, is such that the velocity at the circumference is 5,000 to 6,000 feet per minute. A vitrified wheel weighs approximately 144 pounds per cubic foot.

The best bauxite for the manufacture of abrasive material is found in the south of France, and the furnaces of the Carborundum Company are located near the mines at Sarrancolin, in the foothills of the Pyrenees, power being obtained from a hydro-electric installation which develops about 8,000 horse-power. The furnace product is shipped to Manchester and worked up into grinding wheels at the Trafford Park works. The bauxite deposits of Antrim are unfortunately too variable in composition to be utilised for making abrasives, and have proved equally unsuitable for producing pure alumina for the manufacture of aluminium. A large quantity of the grinding wheels manufactured in America are made from French bauxite.

Whilst used primarily as an abrasive, fused bauxite may be made into an excellent refractory, and the alundum ware produced by the Norton Company is extensively used for the tubes of small resistance furnaces, crucibles, pyrometer sheaths, etc. In making articles of this kind, the powdered alundum is mixed with a suitable bond, and the object moulded from

the mixture and afterwards fired. The product so obtained has a low coefficient of expansion, and withstands sudden changes of temperature far better than porcelain, but not so well as silica. It is relatively a good conductor of heat, which property fits it for the purposes named; and its high melting-point—2050° C.—renders it suitable for work at temperatures which would cause fused silica to devitrify. It has the further advantage of being inert towards platinum at high temperatures, and is therefore suitable for platinum-wound resistance furnaces. Ordinary alundum is porous, and this property has been put to use for filtration purposes in laboratories, the liquid to be filtered being poured into a crucible, in the pores of which the finest particles of precipitate are retained. As the alundum is unattacked by most acids, solutions may be filtered which would destroy filter papers. Porosity, however, is a drawback in the case of a pyrometer sheath; and to overcome this the Norton Company have introduced a non-porous variety, which resists the entry of furnace gases even at high temperatures. In the form of various articles, alundum has now become firmly established as a useful laboratory material.

[Samples of laboratory ware made of alundum were exhibited by Messrs. Townson & Mercer; and of aloxite abrasives by the Carborundum Co., Ltd.]

Artificial Graphite.

Natural graphite, under the names "plumbago" and "black lead," has long been used in the arts for the manufacture of crucibles, lead pencils, and compositions for coating metals. As found, it is associated with minerals such as oxide of iron, silica, alumina and lime, which it is difficult entirely to remove. Moissan was one of the first to notice that ordinary amorphous carbon could be converted into graphite by the aid of intense heat; but the commercial production of artificial graphite was due to Dr. E. G. Acheson. On examining the products of the hottest zone of his carborundum furnace, Acheson noticed crystals of graphite, formed as pseudomorphs of carborundum. This observation led him to make experiments with a view to the production of graphite in quantity, which resulted in the invention of the graphite furnace in 1896. Works were established at Niagara, and at the present time the output of Acheson graphite is several thousand tons per annum. The process of manufacture consists in passing a powerful electric current through coke, anthracite coal, or carbon obtained from petroleum residues, producing a temperature of 3700° C., which suffices to convert ordinary carbon into graphite. The materials are placed in a loose-walled furnace, which can easily be dismantled to remove the products; and at the temperature employed most of the impurities volatilise and escape as vapours through vents in the walls. When the process is complete, carbon vapour begins to come off, giving a distinctive tint to the escaping fumes. When articles of definite shape are required, such as plates or rods, they are first formed into shape from a mixture of finely-divided carbon and pitch; then baked to carbonise the pitch, and subjected to the current in the furnace. The carbon is changed into graphite without the article losing its shape, and incidentally nearly all the impurities vaporize, leaving graphite of 99 per cent. purity.

Artificial graphite possesses the advantage over the natural variety that it may be produced in large, homogeneous masses, and does not require any binding materials. It may be machined with ease by ordinary workshop tools; thus it may be turned in the lathe to any desired shape or size, and may be filed, drilled, and threaded. Ordinary carbon, however prepared, is much more troublesome to work, and soon destroys the tool-edge. A comparison between Acheson graphite and amorphous carbon, with respect to physical properties, is appended:—

Property.	Acheson graphite.	Amorphous carbon.
Specific resistance, ohms per cubic centimetre .	0·000813	0·00325
Specific resistance, ohms per cubic inch . . .	0·000320	0·00124
Comparative sectional area for equal resistance	1	3·8
Specific gravity . . .	1·59	1·56
Tensile strength of rod, lengthwise, lb. per square inch. . . .	800-1000	1000-1500
Temperature of oxidation in air	640° C.	500° C.

It will be noticed that the most striking change resulting from the conversion into graphite is the improvement in electrical conductivity, which is increased nearly fourfold. The specific gravity is slightly raised, whilst the tensile strength is reduced and the temperature

of oxidation made higher by 140° C. For most purposes for which graphite or carbon might be used alternatively, the differences in properties indicated, on the whole, are in favour of graphite, which, however, is more costly than ordinary carbon. The thermal conductivity of graphite, taking the mean of a number of widely-differing results, is about ten times as great as that of ordinary carbon. The uses of artificial graphite will now be considered under separate headings.

Graphite Electrodes for Electrolytic Work.—In the electrolysis of solutions such as common salt, in which nascent chlorine is liberated, anodes of artificial graphite are superior to others, not being attacked by chlorine. In other cases in which corrosive substances are liberated by the electrolysis, such as the recovery of copper and nickel from residues, the same superiority is shown, and consequently artificial graphite is extensively used in such cases. A further advantage in this connexion is the ease with which it may be machined into shape, and fitted with leads for conveying the current. Electrodes of this material do not easily disintegrate mechanically, but are not suited for cases in which oxygen is liberated at the anode.

Graphite Electrodes for Metallurgical Work.—In the reduction of metals from their ores by the electric furnace, the usual procedure is to mix the ore with carbon on the bed of the furnace, and to pass a current through the mixture. The current is led into the furnace by graphite or carbon electrodes, and the points of superiority in favour of the former are (1) better electrical conductivity, enabling a much thinner electrode to be used, and (2) less waste from oxidation in the hot zone. These factors are sufficient in many cases to lead to a preference for graphite, in spite of its higher cost. As the electrodes wear away they are fed forward, and by screwing a new one into the end of the one in use, when the latter is getting short, continuity of the current can be secured. This practice is followed for both graphite and carbon electrodes.

Graphite for Dry Cells.—The superior conductivity of graphite renders it more suitable for filling the space between the two plates of a dry cell than carbon. A further advantage is its greater purity, so that it is not liable to cause local action. Special grades of graphite powder are made for this purpose, and find a wide application in cells for flashlights, telephones, and numerous military purposes.

Graphite for Paints.—There is probably no type of paint so suitable for preserving iron from rusting as one possessing a graphite basis, and natural graphite has long been employed for this purpose. The artificial variety is now largely used in paints, and is claimed to possess preservative properties equal to those of plumbago, in addition to a greater covering power.

Graphite Lubricants.—The use of graphite as a lubricant, mixed with oil or grease, is an old-established engineering practice, and natural graphite, specially purified for this purpose, such as Dixon's graphite, has given such satisfaction that replacement by artificial graphite, even if the latter possessed greater merits, would be difficult. Nevertheless, artificial graphite has found a certain application as a lubricant in the forms of "oildag" and "aquadag," both of which were introduced by Dr. Acheson. The graphite used in these cases is first ground down to a powder which will pass through a sieve of 40,000 meshes to the square inch, and afterwards treated chemically so that it forms a colloidal suspension in oil or water. Graphite of this character is said to be "deflocculated," and when suspended in a liquid will pass readily through a filter-paper. When added to oil the lubricant "oildag" is formed, and its use on a bearing results in the production of a thin layer of graphite on the rubbing surfaces, which, when formed, enables efficient lubrication to be carried on with a greatly diminished feed of lubricant. "Oildag" has been successfully used for many purposes, and Professor Boys, F.R.S., has found it to be highly suitable for delicate mechanisms, such as clockwork. For heavy engineering work, however, it has not yet replaced natural graphite to any great extent in this country. "Aquadag" is colloidal graphite suspended in water, and is recommended as a substitute for oil or soapy water in wire-drawing, drilling metals, and metal turning, being said to be more efficient than either for this purpose.

Miscellaneous Uses of Artificial Graphite.—Tubes for small electric resistance furnaces, muffles and crucibles for laboratory use, and pyrometer sheaths for withstanding extreme temperatures, may readily be constructed from Acheson graphite, owing to the ease with which it may be worked. Such appliances are in daily use, and have added greatly to the possibilities of conducting work at temperatures which would be destructive to ordinary metals or refractories.

[Specimens of artificial graphite in various forms were exhibited by E. G. Acheson, Ltd.]

Vitrified Silica.

When rock-crystal or sand is heated to fusion, and allowed to cool, it remains in a vitreous condition, and then possesses properties resembling those of glass. Vitrified silica thus prepared softens perceptibly at 1500° C., but is not completely melted until nearly 1800° C., and whilst in the plastic state it may be drawn out and blown in the same manner as glass. Boys was the first to employ vitrified silica for a practical purpose, and made very fine filaments of the material by shooting pieces from a softened quartz crystal with a crossbow, producing threads more suitable for delicate galvanometer suspensions than had hitherto been in use. Shenstone in 1901 carried the matter further by making tubes from a bundle of rods by fusion with the oxy-hydrogen blowpipe. A year or two later Heraeus in Germany and the Silica Syndicate in London made great advances in the blowpipe treatment of pure quartz, and introduced laboratory apparatus of transparent silica, such as flasks, crucibles, and test-tubes. The cost of such articles was somewhat prohibitive, owing to the high price of pure quartz and the expenses of manufacture; but the remarkable property of vitreous silica, whereby it may be quenched in water from a white heat without cracking, led many workers to attempt to produce it more cheaply by using a pure form of sand. Practical success was first achieved in this country by the Thermal Syndicate at their Wallsend works, an electric furnace being employed to melt up sand containing 99 per cent. of silica. In making tubes, for example, a current of sufficient power is passed through a graphite core surrounded by the sand, which is fused to a depth determined by the time the current passes. Care must be exercised not to exceed a temperature of 2000° C., as otherwise there would be a danger of the carbon and silica reacting to form carborundum. The core is then withdrawn, and the plastic mass pulled out into tubes of the required dimensions. By arranging the shape of the core, pieces with closed ends can be made, and afterwards blown in moulds to any desired shape by means of compressed air. A weight of 200 pounds of fused silica can now be produced and manipulated, thus rendering it possible to manufacture articles for commercial processes. A similar method is now followed in making transparent silica from pure quartz.

Silica articles made from sand are not nearly so transparent as those from quartz. This is due to the presence of air bubbles derived from the sand, which are unable to escape through the fused mass. For this reason the specific gravity is lower than the air-free product obtained when pure quartz is used, the figures being 2·07 and 2·2 respectively. The coefficient of expansion, however, is practically the same in both cases (52×10^{-8}), or only $\frac{1}{17}$th that of glass; so that the resistance to fracture due to sudden changes of temperature is the same in both varieties. As in most of the uses to which vitreous silica is applied transparency is not essential, the cheap material made from sand meets nearly every requirement, and has proved most valuable for a variety of purposes, both chemical and electrical.

Vitrified silica, from the chemical standpoint, possesses the valuable property of being proof against acids, with the exception of hydrofluoric, and phosphoric above 400° C. This fact, combined with its capacity for withstanding changes of temperature, has enabled it to replace with advantage porcelain and earthenware in industrial chemical processes. In the best modern plant for the manufacture of nitric acid from saltpetre, the product is condensed in silica pipes, which may be water-cooled without danger of cracking; and in concentrating sulphuric acid silica basins are now used. The production of the enormous quantities of these acids needed for the manufacture of explosives has been much facilitated by the use of silica apparatus; and in addition the output of vessels and pipes of various kinds has proved of advantage to chemical industries generally, in all cases where acid and heat-resisting properties are of importance. A further advantage of silica ware is that it is non-porous. It is attacked, however, by alkalies, either fused or in solution.

In the laboratory, silica apparatus, either of the transparent or semi-transparent type, is much used instead of glass for various kinds of vessels and combustion tubing, in cases where heat-resistance is of importance; and as a substitute for porcelain in crucibles, basins, combustion boats, etc., as, unlike porcelain, it is not liable to crack on sudden heating. Practically all glass apparatus may be reproduced in silica. One of the most useful applications of vitrified silica is in connexion with small electric furnaces of the resistance type, in which a tube or muffle of silica is wound with nickel-chrome wire or strip, and insulated thermally by asbestos or other material. In these furnaces a temperature of 1000° C. may be attained with a small expenditure of current,

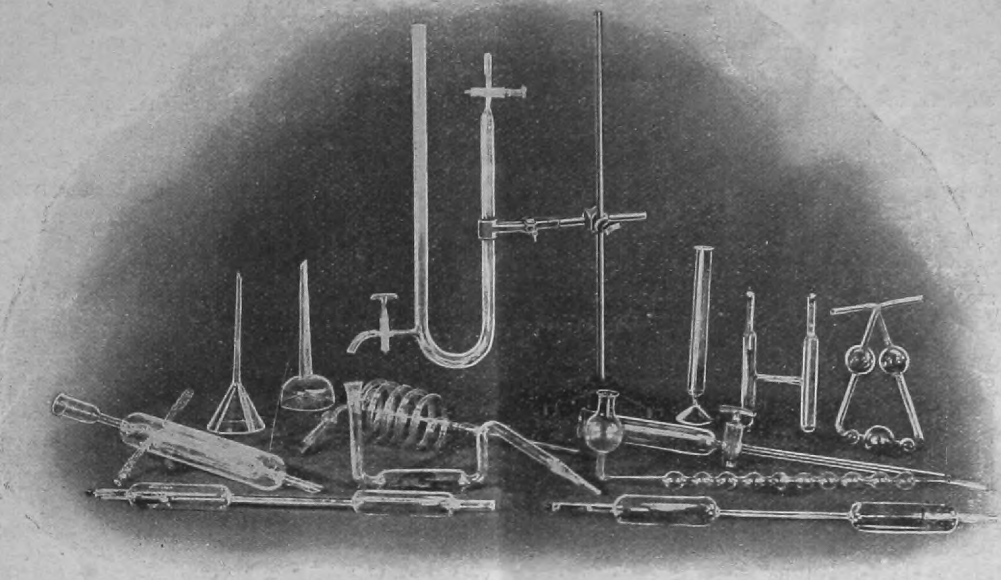

FIG. 9.—GROUP OF ARTICLES MADE OF TRANSPARENT SILICA.

and they are now extensively used for chemical combustions, and for the heat treatment of steel articles such as dies, taps, and gauges, where a precise temperature regulation and clean atmosphere are required. The advantage of silica in this relation is that there is no danger of cracking when the current is switched on. The present lecturer was one of the first to use silica for this purpose, and soon afterwards Bastian applied the idea to electric radiators for warming rooms, this form of heater having now almost entirely replaced the large carbon-filament lamps formerly used.

Silica sheaths are largely used for protecting the wires of pyrometers, and not being penetrated by furnace gases, are well suited to this purpose. Silica, however, if heated for a long period above 1200° C., undergoes devitrification, and is liable to weaken and crack, so that its use in pyrometers is restricted to temperatures below 1200° C., except for occasional readings.

Another useful application of silica has been found in connexion with lighting, as a substitute for glass in chimneys and bulbs. The semi-transparent variety is used to surround gas-mantles, the chimneys being of less diameter than would be permissible with glass. The result is that the mantle becomes hotter and more luminous, and the light is softened by passing through the material. For electric lamps of the "half-watt" variety, which contain nitrogen, clear silica has been used, resulting in the production of a much smaller lamp than is possible when glass forms the enclosure. For scientific work, vacuum tubes of clear silica have been constructed, the electrodes being made of molybdenum wire, sealed in position by a special joint of metallic lead.

There are many other instances in which vitrified silica may be used to advantage, and there is little doubt that its use will extend as improved methods of production bring about an accompanying reduction in cost. The gratifying fact that this country has always been to the fore in the production of silica ware is due to the enterprise of the Silica Syndicate, who have specialised in the clear variety, and the Thermal Syndicate, who have produced the cheaper form under the name of "Vitreosil." Examples of silica articles are shown in Figs. 9 and 10.

[Specimens of clear silica ware and "vitreosil" articles were exhibited at the lecture by the Silica Syndicate, the Thermal Syndicate, and Messrs. Johnson & Matthey.]

HIGH TEMPERATURE PROCESSES IN BRITAIN.

It will be recognised by all who have studied the matter closely that the future industrial success of any country will largely depend upon the extent to which it develops high temperature processes. Most of our advisers in connexion with after-war policy agree in stating

that increased production will be essential if we are to recover our financial position; but this is a conclusion which requires qualification. Merely to increase production in the case of existing industries would probably lead to over-production, and almost certainly to stagnation. Increased production there certainly must be, but additionally, if we are to hold our place, new industries must be developed, amongst which work at high temperatures will play an important part. The remarkable growth of electric steel furnaces in this country during the last four years is an indication of the trend of events which we cannot afford to ignore; and the ever-increasing importance of high temperature products serves further to point out the direction in which effort will be necessary. One of the first essentials will be a cheap and abundant supply of electricity, and it is to be hoped that not only the sixteen super-power stations proposed by the Coal Conservation Committee, but many others, will be erected, entirely apart from considerations of economy in coal. The question as to how far we shall be able to compete with other countries possessing abundant water-power is one that cannot be generally answered, as each process must be considered separately in relation not only to heating costs, but also labour charges, proximity of raw materials, freights, etc. In the paper recently read before the Society by Mr. Newlands on "Water Power in Great Britain," it was shown that the unused water-power in Britain amounts to at least 400,000 horse-power; but the drawback is that the sources are scattered and in most cases remote from centres of supply of necessary materials. Whilst in some localities it might be possible to establish special industries, there is little prospect of competing in water-power installations with more favoured countries such as Norway and Switzerland; and it would appear that we must rely upon our supplies of fuel for generating electricity on the large scale. A typical example is furnished in the case of calcium carbide, now an indispensable material for the production of acetylene, in addition to its other uses. To manufacture one ton of this material involves a consumption of 4,000 kilowatt-hours, the cost of which at the hydro-electric installations in Norway is about £1 5*s.*; whereas the fuel costs in this country, even in a good power-station, are about ·35*d.* per unit, or £5 16*s.* per ton of carbide. This difference, after allowing for freights and other costs, is sufficient to throw coal-generated electricity out of competition for producing carbide. Schemes are put forward from time to time for treating coal in such an advantageous manner as to obtain heat practically for nothing, by gasefying in special ways and recovering by-products; but so far none of these have proved successful in achieving this end. It may be possible to accomplish this, but judging from past experience we should be unwise to rely on this solution of the problem. Mr. Chas. Bingham, who is well known as an authority on

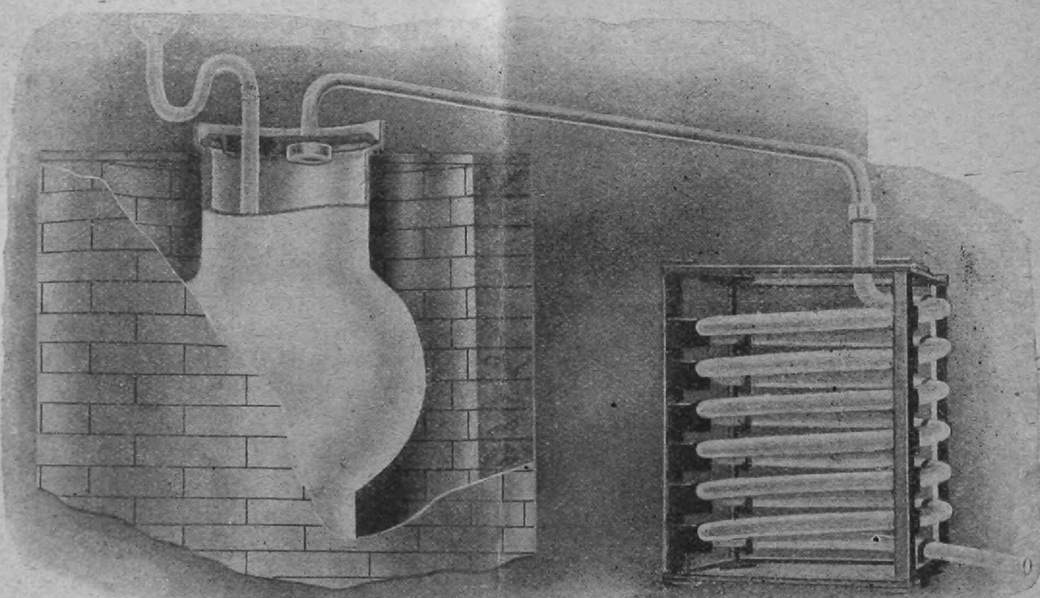

FIG. 10.—RETORT AND CONDENSING COILS MADE OF SILICA.

calcium carbide, has pointed out that the surplus gas from blast furnaces and coke ovens, over and above that which can be utilised for various purposes on the spot, amounts in the aggregate to a very large quantity. If, therefore, the carbide furnaces could be established in proximity to blast furnaces, power should be obtainable at a rate sufficiently cheap to enable carbide to be produced economically in this country. The amount of heat wasted industrially is appalling; and any suggestion of a practical nature to utilise this waste should be welcomed.

In considering other high temperature products such as carborundum, the heat costs do not bear such a high ratio to the cost of the finished article as in the case of carbide, as the raw material is treated in various ways before marketing. In a case of this kind the disparity in the cost of production becomes proportionately less, and taking into account items such as freight and access to raw materials, competition with hydro-electric power becomes a possibility. Moreover, it is now possible to purchase electric power as cheaply at Newcastle as at Niagara, the great centre for electric furnace products; and there appears, therefore, to be no economic reason why carborundum and graphite, for example, should not be manufactured in England. The development of cheap power schemes should lead to the establishment of many new industries in this country, provided the necessary enterprise and capital be forthcoming.

High Temperature Research.

One effect of the war has been to create a general appreciation of the value of research in connexion with industry, and efforts have been made in many directions to make good our previous negligence in this respect. Although it is not always possible to distinguish between "pure" and "applied" science, there is no difficulty in recognising the difference between a research which has only in view the discovery of new phenomena, and one intended to cheapen or to develop industrial production. Both types of research are essential to progress, for the laboratory discovery of to-day may become the commercial process of to-morrow. Our fault in the past has probably been that our leading exponents of science have devoted themselves almost exclusively to "pure" science, with the result that many industries have suffered owing to the absence of the continuous research necessary for success under modern conditions. So far as high temperature processes are concerned, our record is not one of which we may be proud, as, with the exception of silica ware and aluminium, we are dependent on other countries for materials which have now become indispensable. The chief reason for this has no doubt been the absence of cheap electricity; but now that this is to be remedied no time should be lost in commencing high temperature research on various lines. Amongst problems awaiting solution may be mentioned the smelting of tungsten and other metals of very high melting-points, and the formation of alloys of these metals, the production of suitable refractories for use in electric furnaces generally; and the manufacture of the diamond on the large scale for abrasive purposes. Apart from these obvious lines of research, the production of new compounds as the result of high temperature reactions offers a boundless field for investigation, and should lead to important industrial developments. It is only necessary to consider the results which have accrued from the heating of coal and lime, coal and sand, and carbon alone, in the electric furnace, to realise the possibilities in this direction, and the imperative need for research on the lines indicated.

A commencement has been made by the installation of an electric furnace at Sheffield University, of sufficient capacity to enable experiments on steel to be carried out on an industrial scale. A good electric furnace, capable of taking charges which would enable commercial possibilities to be deduced, should be installed at all the leading centres of scientific instruction; and wherever possible the work should be carried out in co-operation with the industry involved, as in the example set by Sheffield. One or more such furnaces, devoted to general research, should be established in London; and, speaking from personal knowledge, there would immediately be many firms desirous of submitting problems, the solution of which would be an aid to the industries in which they are engaged. The erection of suitable furnaces and the charges for current and upkeep would be considerable, but the results would repay the costs many times over. This is a matter which might well engage the attention of the numerous scientific societies in London, with a view to conjoint action, unless some public benefactor may be found who will provide the necessary funds. In the provinces other centres may be relied upon to continue the movement initiated by Sheffield, and it is to be hoped that

before long high temperature research will be flourishing in this country as it has been for some years in America. The factories at Niagara, with their enormous output of various materials, are the outcome of this research, and given adequate facilities in this country for investigation, there is no doubt that we should reap our full share of the future developments which are certain to arise in this field of work. On the other hand, failure to commence work in this direction, or undue delay, will probably lead to serious commercial drawbacks, and place us at a disadvantage as compared with our trade competitors. For the future of industry lies largely with high temperatures.

INDUSTRIAL DEVELOPMENT IN INDIA DURING THE WAR.*

By D. T. Chadwick, I.C.S.,
Indian Trade Commissioner.

It is a well-known truism to say that India is primarily an agricultural country. Except for the large cotton, jute and coal interests, industries in India in the early years of this century were either confined to a few factories or were still continuing on a village scale. Thus in the year before the war, in the sixteen principal articles of export of a total value of £150 millions, only two classes of manufactured goods figure, viz., cotton and jute. On the other side, except for sugar, the principal imports consisted solely of metals and manufactured goods, among which cotton and iron or steel goods took leading places. It was thus not surprising that on the outbreak of war the first economic anxiety centred round the difficulties of selling agricultural produce, for though most of the crops were sown, it seemed that, by the time they came to harvest, markets would be either non-existent or very restricted. For some articles these forecasts proved true. Difficulties have continued, and in some cases become more intensified, yet on the whole this stage soon passed as it became clear that many of India's raw products were essential for the prosecution of the war—as, for instance, jute, wheat, wolfram, lac, mica, castor seed, hides, etc. The first phase of the second stage supervened, viz., the need for a greater and more varied industrial output from India. The causes which called for this effort are still acting, some with increased force. They are, briefly, the need of supplying from India, as far as possible, many of the requirements of the armies operating in the East, and the necessity of supplying local wants for which the ordinary sources of supply are cut off, either through lack of shipping, or through being otherwise engaged. The industrial effort thus called for has taken three forms: (1) the establishment of new factories or the expansion of existing ones, (2) the organisation of such industrial resources as India possessed, and (3) the closer examination of local resources in the search for substitutes, etc. It is far too early to attempt a full account of India's economic efforts during this time of war. That story I hope will be told some day. Nor is an exhibition of scientific products the time to dwell on the business organisation of this effort —rather, I will attempt to indicate a few of the main lines on which inquiries for the greater utilisation locally of India's own resources have proceeded. Unfortunately there has not been time to obtain complete exhibits from India. Many of the inquiries I shall refer to will necessarily seem to be on a lower plane than the scientific inquiries undertaken during this war in this country; but the results are likely to be as relatively important to India as those obtained here, according to all our hopes, will prove important hereafter to this country.

Even before the call for widespread organised industrial effort was made the larger factories in India had contributed most helpfully to Army supplies. The jute-mills of Calcutta supplied many of the millions of sandbags and yards of sacking required, whilst almost from the outset of war Indian cotton-mills met the needs of khaki cloth, etc., for the ever-increasing armies in the East, which for khaki cloth alone now run to over twenty million yards a year. In the first half of 1915 the railway workshops, as well as those of the principal engineering firms in Calcutta and Rangoon, undertook to supply shell-cases to supplement the output of this country. And this continued until the Ministry of Munitions in England had so developed its own organisation as to be independent of any supplies from India. It was fortunate at that time of anxiety that India could to some extent help. But it was only just rendered possible. The steel used, which was according to United Kingdom specification, was all supplied by the Tata Iron and Steel Company, and was of such quality that not a single shell was rejected at gun proof for defective steel. Without these steelworks India could not have rendered such aid; yet these steelworks were

* Delivered at the British Scientific Products Exhibition, September 3rd, 1918.

only erected in time. The first steel ingot at these mills was only rolled in February, 1912, and the first rails a month later, *i.e.* a little over two years before the outbreak of war. Some time is always needed for a steel factory to get settled down to work, especially when it is the first of its kind in a country, and all labour has either to be imported or trained, and still more when, in addition, the whole site of the works, mines, etc., was tropical, and practically uninhabited jungle only four years previously. The utility of these steelworks did not cease with the provision of steel for shell-cases. They have been the chief source of supply of rails for Mesopotamia and Africa. Extensions of the works have been undertaken, and a rolling-mill is being erected which will give steel plates of any length and up to 90 in. in width. A supply of such plates obviously opens a large vista of future possible developments. In addition, the Bengal Iron Company has helped largely, and now another iron and steel company has been formed under strong auspices to develop other large iron deposits. Without these steelworks India's contribution of finished material to the armies in many parts must have been very much less than it has been, and the burden would then have been thrown on this country. These instances of sandbags, khaki cloth, and steel, serve to illustrate in a small way how the wise development of industries in India on modern lines not only benefits that country by establishing a better local balance of employment, but is a source of strength to the Empire in general in a time of need.

The cases so far quoted relate to large firms in existence when war started. But as time went on, more widely co-ordinated efforts were needed to supply as far as possible essential articles both for the armies and the civil population. For this purpose the Indian Munitions Board, under the able control of Sir Thomas Holland, was started in April, 1917. It was clearly a great undertaking to attempt to organise industry in war time in a country in which over 70 per cent. of the population were normally engaged in agriculture, and in which there are at least twenty-three different languages, each of which is spoken by more than a million people. It was impossible to make India self-supporting in manufactured goods in the time, and no such visionary ideals were entertained. But very much more has been achieved alike in quantity, quality and variety than three years ago seemed possible. This result has been largely due to the whole-hearted and ready co-operation and help which the business community in India of all classes and grades has given to the Munitions Board. As one instance of the speeding-up which has resulted from such co-operation, it may be said that the Karachi Committee took about six weeks to convert a vacant tract of foreshore into a village with workshops, workmen's houses, etc., complete for the re-erection of sectional barges. And whilst at first nineteen days were required for the re-erection and launching of one barge, some few months later they were rarely turned out at a rate of less than four a week, and at times a speed of six a week was obtained.

The realm of forestry is one which has come in for searching examination during this period. In spite of a forest area of over 250,000 square miles, imports of timber into India exceeded exports by some twenty to thirty thousand tons a year before the war, excluding firewood, railway sleepers and ornamental woods. These imports consisted largely of teak, hardwoods and pine. In one instance even wood was imported from Siam when exactly the same was available locally at lower price. This extensive employment of imported timber has been ascribed to a general want of sufficiently precise information regarding the timber resources of India. This defect could not be remedied in a day, but the present vital need of developing local resources has drawn great attention to it. Timbers have been found locally which even meet the high specification required for aircraft, though for this use the specific gravity requirements are defined within such narrow limits as to restrict the range of choice. These have now to undergo searching practical test. Two timbers are being tested practically, as they are expected to prove suited for rifle manufacture, whilst in the lower categories much of the imported pine and fir could be replaced in ordinary scantling sizes by the pine and fir of the Himalayas. A substitute even for Oregon pine is available if improved engineering facilities are afforded. Meanwhile stocks of timber cut to sizes have been accumulated in various ports, and the Indian Munitions Board, since its inception, have sent overseas for Army purposes more than twice as much Indian timber as was ever exported in time of peace. The work of the Forest branch has not, however, terminated here. Researches and trials have been continued as to the best ways of preserving bamboos—a most important issue

in any tropical country. Increased attention has also been paid to the resin and turpentine industries in North India, and the resin now produced in the Punjab has recently been pronounced by a commercial firm in London as superior in some respects to that from France. Whereas before the war India imported annually some 3,000 tons of resin, the local output has now been more than doubled and is about 2,500 tons. Similarly, in regard to turpentine, the local supply has been more than doubled, and now exceeds 120,000 gallons. The increases have been attained largely by improved methods, and after the war, when again it becomes possible to obtain machinery, much larger quantities should become available. Inquiries are being pushed on in co-operation with business houses in other directions in which forest resources are essential to industries, as, for instance, in substances suitable commercially for some grades of paper pulp, in wood distillation, and in the testing and exploitation of tanning materials. In regard to sandal-wood oil, the Mysore Government seems to have captured one trade which hitherto had largely centred in Germany. Before the war, sandalwood to the value of over £100,000 was exported annually. The factories established in Mysore since the war are now capable of turning out nearly 20,000 lb. weight of oil a month of the highest quality, well suited for medicinal purposes. Within eighteen months of its inception, the monthly turnover had reached £20,000. Considering that the export of oil instead of wood means a saving of some 90 per cent. in freight, and that oil of high quality is now made, it is reasonable to hope that this industry will remain in India.

For tanning materials, efforts have proceeded on three main lines :—

(1) Encouraging the cultivation by special concessions of *cassia auriculata*, the favourite tanning reagent in Madras.

(2) The preparation of tannin extracts, especially of myrabolams, for hitherto the raw fruit has been exported, and not the extract.

(3) The systematic inquiry and testing at the factory at Maihar of numerous other tannin reagents and combinations thereof. These form a very important line of inquiry, as India has a very large output of hides. The undue weighting of hides and damage by faulty flaying have often proved a heavy handicap to Indian kips. It cannot be pretended that these difficulties have been entirely or effectively surmounted, but all exports tend to show that a vast improvement has occurred owing to control and the need of working to the high Army specification. Concurrently there has been a large increase in the output of leather goods of all kinds, many of which had not hitherto been made in any quantity in India—from the many articles for military equipment to leather belting and pickers for cotton-mills. The Cawnpore leather factories are among the best known in India, but others are being erected with modern equipment, especially round Calcutta.

In an entirely different category come a large range of medical stores and surgical requirements. In spite of the vastly increased demand for these articles, many which were previously imported are now entirely manufactured locally ; among these may be cited loose woven bandages, absorbent cotton wool and yarn, etc., and gauze, double cyanide, compressed and uncompressed, carbolised and boric wool, and many forms of bandages, etc. The glassworks in the north have been able to make satisfactory Petri dishes, glass tubings and flasks, whilst attached to the Medical Store Depôt at Bombay is a private concern employing some hundreds of workmen in the manufacture of artificial limbs of the most approved modern type. Very similar progress has been made with drugs. Whereas before the war, absolute alcohol, refined petroleum, lysol, etc., and many of the preparations from belladonna, and nux vomica, were entirely imported, they are now being made satisfactorily in India. Thymol, ether for pharmaceutical purposes, quinine hydrochloridum, acidum, strong ammonia, etc., are all now obtainable locally. Many other medical essentials have been made in limited quantities, as, for instance, amylum from rice, tannic and gallic acids, salicylic acid and its sodium salt, and methyl alcohol, etc.

(*To be continued.*)

INDUSTRIES AFTER THE WAR.

II.—ENGINEERING.

The recently-issued report of the Departmental Committee appointed in July, 1916, to consider the position of the engineering trades after the war is very comprehensive, and with statistical tables extends to upwards of fifty pages. The earlier and not least interesting sections deal mainly with the pre-war conditions of the trade. The only particulars available as to the magnitude of those

branches which formed the subject of the Committee's investigations—the electrical industries and marine engineering, for example, were referred to separate committees—are those compiled under the First Census of Production and relate to the year 1907. The gross value of the output, including duplications and cost of all materials used, was given as about £168,500,000, and the net value, excluding duplications and cost of materials, as about £84,000,000. The real value lies between these two figures, and is put at about £144,000,000 including cost of materials but free from duplication. The number of male persons employed in engineering generally at the outbreak of war was 812,000, of female persons 52,000. In October, 1916, the figures had risen to 918,000 and 233,000, 85 per cent. of male and 90 per cent. of female labour being employed on Government work. The totals include those working in national factories, approximately 114,800 men and 99,000 women, according to information available when the report was written, eighteen months ago. "There is no doubt," the Committee observe, that "on light work involving repetition, female labour is quite as good as male labour. Although some employers have, for various reasons, expressed their unwillingness to continue to employ female labour after the war—reasons which do not seem to us always good ones—there is no doubt that most employers will be anxious to continue to employ female labour on the lighter repetition work." Indeed, it seems to the Committee that the continuance of a certain amount of female labour is "both necessary and desirable."

As regards the position of the industry immediately after the war, the employment of practically the whole of the engineering firms in the kingdom upon munition work has necessitated the installation of large quantities of machines, some bought in the United States of America, some made at home; plant already in position has been disturbed and rearranged, and there has been a general dislocation of the scheme of manufacture as hitherto carried out in many works. Generally speaking, it is not anticipated that the additions will much strengthen the position for post-war purposes. Much of the plant has been put down for shell work, and the grouping and balance of machines for this manufacture are unsuitable for other purposes, and many of these will be of little use for general engineering work when the war is over. Many of the machines bought early in the war were of too light a type and have not stood the heavy work put upon them. It may be assumed that even the heavier machines have suffered from continuous work, and will be in a worn condition, urgently needing repair; and it will be some considerable time before it will be possible for the engineering works throughout the country to resume the regular current of their normal work. With regard to the buildings that have been erected, they are generally light in character, but will be useful where medium and light trades are carried on.

The knowledge that work is being done by controlled firms without competition has produced a feeling amongst workmen—and, indeed, amongst the staffs—that, as the Government pays, the rates of wages can be indefinitely increased, and that no particular attention need be paid to cost. In the necessary pressure to produce work urgently required, many concessions have been made in the matter of wages, with the consent of the authorities, which would be impossible in normal working. The controlled firms, when the control is lifted, will have the greatest possible difficulty in reorganising their pay-sheets upon anything like normal working lines. There is the further possibility that some portion at least of their output will, after the war, be earmarked for the necessities of the reconstruction of Belgium and the invaded portions of France. All these things seem to the Committee to entitle the controlled firms to special consideration.

As a matter very relevant to the consideration of international competition after the war, the Committee think it necessary to refer to the great growth of engineering works in Canada since 1914. With a population of eight millions, Canada is said to be equipped with engineering works capable of dealing with the wants of twenty-four millions of people. "If this is true," say the Committee, "the competition of Canada may hereafter have to be included in any reckoning of international trade." Moreover, intelligence, enterprise, and cheap labour combined, may easily make Japan a formidable competitor, in spite of her relative lack of coal and ironstone.

Among the witnesses examined, the larger and more prominent firms naturally predominated. This might give a somewhat false impression of the size of the units carrying on the engineering trade in this country. Actually, the smallness of the individual firms and of the capital they employ was most noticeable. "There are, of course, exceptions, but on the whole it is clear that the engineering trade of this country is in smaller hands than in the United States of America and in Germany, though the difference is probably not so great as in the coal and steel trades." It appears to the Committee that before the war there was a considerable proportion of plant in existence which would not represent anything like the value at which it appeared in the owners' books, and was not turning out enough work to be economically employed. Such plant is still in existence.

Throughout the evidence the Committee were confronted with large purchases before the war from the United States of machine tools unobtainable here, or if obtainable at long delivery only. Since the war considerable strides have been made in the manufacture of these articles, and witnesses who had bought special tools abroad before the war admitted that they were now able to obtain some types of them at home.

While advocating research at the universities the Committee declare that no trade will be progressive that relies entirely upon outside assistance for

experimental work and the investigation of new problems. "If the engineering business cannot be organised on such a scale that the larger firms could have adequate scientific departments, then we should recommend that some collective effort be made to establish such a department by a combination of firms in the same branch of trade, and we know that this has been successfully accomplished in Germany."

As to imported materials, the Committee say that the real motive actuating the purchase of many of the articles alluded to was varyingly based on quality, price and delivery, as to all three of which the British purchasers were insistent on the superior advantages offered by foreign countries. "There seems to be no reason why, in the large majority of these cases, this country should not in future shake itself free from all dependence on outside sources, provided that works organised to produce these articles are on large enough scale."

The summary of recommendations with which the report ends includes the following :—

"To give time for the reorganisation of the engineering works of this country on a business footing after the war the importation of enemy engineering products into the United Kingdom be prohibited, except under license, for a minimum period of one year and for such longer period as may be deemed expedient.

"To encourage trade between present Allies they be invited, without interference with their existing fiscal systems, to consider the imposition of an additional duty or surtax over and above their normal duties, to be levied solely against the products of the present enemy countries, such surtax to be subject to progressive diminution.

"That this country impose a duty equal to such surtax on the products of present enemy countries and to be subject to like progressive diminution.

"That raw materials be admitted to this country duty free.

"That a Government Department be charged with the duty of exercising vigilance over the adequate provision in this country of manufactures, as distinct from our staple trades, which are at any time essential to the national safety: such as tungsten and magnetos.

"That the development of the supply of raw materials within the Empire for such essential industries be supervised, encouraged and assisted by the Government.

"That all necessary steps to protect such essential industries be taken by the Government whether by prohibition, tariff protection or subsidy.

"That 'dumping' of goods as defined by American Law be prohibited by legislation.

"That the Government control of industries be lifted as soon as possible after the war, having regard to the interests of the manufacturers. That allowances under the Munitions Act be made with particular regard to the necessity of leaving firms unimpaired for the conduct of post-war competition in the export markets.

"That it should be the recognised duty of Government Departments, municipalities and corporations, to purchase, as far as possible, goods only of British origin, due precaution being taken to prevent price rings.

"That in the interests of the country the engineering manufacturers be encouraged to work together in larger units, either by amalgamation or by joint working, by pooling of resources, by specialising production, and by organisation of export sales, and for the purchase of raw materials.

"That standardisation of products should be more widely practised. The work of the Engineering Standards Committee deserves to be assisted.

"That the proposed British Trade Corporation be supported as promising to provide much needed help for the engineering trade.

"That India and the Dominions be invited to concede an effective preference to the goods of the British Empire.

"That all goods of foreign origin should have clearly and indelibly marked upon each article the words 'Not British.'

"That 'Summer Time' be permanently enacted.

"That every effort should be made to develop and encourage the medium and light engineering trades, whether already existing in this country or not; thereby making use of the workshops, motive power and equipment installed for war purposes and finding suitable employment for the large body of semi-skilled and female labour recently created."

MAHOGANY PRODUCTION IN GUATEMALA.

Exact statistics as to the mahogany resources of Guatemala are not available, but it is known that the timber exists in practically unlimited quantities in the northern part of the Republic, known as the Peten country, while another defined zone or belt is found in the western or Pacific coast region. The outbreak of the European war caused a sharp curtailment in the export movement of mahogany, shipments for a time being practically suspended. The country, however, has in a measure recovered from the depression due to the war, and mahogany is again beginnning to move, shipments being confined principally to the United States.

The Usumacinta River, forming part of the Guatemala-Mexico border, is largely employed in rafting mahogany logs to the Mexican port of Frontera, where shipments are made to the United States. The timber is also rafted from the Peten region *viâ* the Belize River to Belize, British Honduras, where exports are made principally to England. Timber in smaller quantities is found along the Gulf coast in the vicinity of Sarstoon and Livingston, the logs from this section going chiefly to the United States.

According to a report by the United States Consul at Guatemala City, a well-defined timber belt parallels the Pacific coast of Guatemala at distances varying from five to twenty-five miles

from the ocean and extending from Coatepeque to the Salvador boundary on the south. San José and Champerico are the principal exporting points for this territory. Much of the timber accessible to transportation facilities has already been cut, and it is estimated that not more than 15,000,000 to 20,000,000 feet remain that would be commercially profitable to export.

Fully 90 per cent. of the mahogany in this region is found within twenty-five miles of the coast. The timber is scattered and is said not to average more than one tree to five acres. The timber is hewn and hauled in ox-carts to shipping points along the Occidente Railway and the division of the International Railways of Central America extending from Guatemala City to San José. The construction of additional railways and the completion of the proposed intracoastal canal, known as the Chiquimulilla Canal, would give impetus and encouragement to the mahogany industry of the west coast. There are many rivers, nearly all of which are navigable for rafting purposes, including the Michitoya, Guacalate, La Gomera, El Naranjo, Coyolate, and several others, which are not utilised at this time for the reason that San José and Champerico are the only licensed ports for the Pacific Coast.

In this region are a number of mills, which saw chiefly mahogany and cedar. Some of the lumber is exported *viâ* San José and Champerico, while shipments are also made to Guatemala City, where several furniture factories are now in operation.

First-rate mahogany f.o.b. San José is worth £16 per thousand feet, of which total cost £2 10*s.* represents the loading charge and the export duty of 8*s.* 4*d.* per ton, and £1 to £3 represents the railway transportation.

The ocean rate on mahogany lumber, Puerto Barrios to New York or Boston, is £3 per thousand feet, and on logs £4. The rate San José to San Francisco or Seattle is about the same.

Producers of mahogany operate under a Government concession, granting them the right to cut and remove timber from a prescribed area.

Mahogany is not separately shown in the customs statistics of Guatemala, but it forms the bulk of all export shipments both of timber and lumber. The report of the Minister of Finance and Public Credit for 1915 shows that lumber to the amount of 3,524,622 quintals (metric quintal = 220·46 lb.), valued at £36,700, was exported *viâ* San José and the frontier custom-house of Peten. For 1916 the total exportation amounted to 2,339,276 quintals, valued at £24,300, all going to the United States.

OBITUARY.

Horace Porter, M.A., F.R.I.B.A.—Mr. Horace Porter, who died on July 29th, at the age of fifty-seven, at his house in Russell Square, became a member of the Society in 1895. He was educated at Uppingham and Trinity College, Cambridge. After taking his degree he studied architecture under his father, Mr. F. W. Porter, and was taken into partnership by him, starting in practice in 1890. About fifty years ago Mr. Porter, senior, was appointed architect and surveyor to the Sun Fire Office, and also surveyor to the Clothworkers' Company. In both offices his son succeeded him. They were responsible for various important buildings in London, including the offices of several banks and insurance companies, as well as for some private country houses.

Mr. Horace Porter was Master of the Saddlers' Company last year. He took a very active part in local administrative matters, having been an original member of the Holborn Borough Council, and Mayor in 1910-11. He was also an energetic Freemason, having been secretary of a well-known London lodge for ten years, and Grand Treasurer of the Degree of Mark Masons. He married, in 1901, Mary, the youngest daughter of the late G. P. Bidder, Q.C., the eminent Parliamentary Counsel.

Frank Garrett, M.Inst.C.E.—The late Mr. Frank Garrett, whose death occurred at Aldringham on August 2nd, was born at Leiston on May 6th, 1845, and educated at Rugby and Stuttgart. He was elected a member of the Society in 1878, an Associate Member of the Institution of Civil Engineers in 1869, a Member of the same institution in 1880, and a Member of the Institution of Mechanical Engineers in 1882. On the death of his father, the sixth Richard Garrett, he became a partner, with his two brothers, Richard Garrett and Henry Newson Garrett, of the well-known business, Richard Garrett & Sons, manufacturers of agricultural machinery and implements. Mr. Henry Newson Garrett retired in 1878, and Mr. Richard Garrett died in 1884, leaving Mr. Frank Garrett the sole proprietor of the business, which, in 1897, for family reasons, he converted into a private limited liability company. Mr. Frank Garrett was a man of very progressive spirit, and as far back as 1867 was producing traction engines with Boydell's patent wheel attachment for taking heavy weights over soft ground. In 1870 he started making malleable castings under Tenwick's patent, and was one of the first, in 1880, to adopt artificial means of drying wood under McNeill's patent. He may certainly be regarded as one of the pioneers of flanging steel boiler-plates by means of hydraulic machinery, having put down a plant for this purpose in the early seventies. In 1880 he took out a patent for his steel corrugated firebox for locomotive type boilers, which not only did away with all crown stays, but was a most efficient firebox, giving an increased heating surface of about a third over the ordinary flat-top box, and forming what may be styled a half-water tube in the midst of the hottest flames. This was to a very large extent copied by German and Austrian competitors. In 1881 Mr. Garrett introduced the

first compound portable steam-engine, which formed the progenitor of the high economy superheated steam semi-stationary engines, now one of the staple products of the firm.

Amalgamation of metals occupied a great deal of Mr. Garrett's attention at one time, and he made extensive and repeated experiments in the mixing of alloys, with a view to determining the best combinations to meet the requirements of various types of bearings.

Mr. Garrett was never idle. When not at work directing his business, he was, besides being a good all-round sportsman, always busy in public work or in helping others. He was a Justice of the Peace for the county of Suffolk, and one of the original members of the East Suffolk County Council, of which he was early made an alderman, taking a great interest in educational matters, and for a long period holding the office of Vice-Chairman of the Technical Education Committee of the Council. He was also for many years Chairman of the Governors of Framlingham College, which, to a large extent by the efforts of his father, was founded in memory of Prince Albert. Under Mr. Garrett's guidance the college rose to its present high state of efficiency. Mr. Garrett was a cousin of the late Dr. Elizabeth Garrett Anderson.

GENERAL NOTES.

EDUCATION IN THE ARMY.—The *Times* understands that Colonel Lord Gorell, M.C., has been appointed to take charge, under Major-General Sir Arthur Lynden-Bell, of a new Department of the Directorate of Staff Duties, which has been formed to direct and to co-ordinate education in the Army. An Inter-Departmental Committee, to which various Ministries have nominated representatives, will advise on general principles, and the Department will have within it a distinguished educationist as civil expert, assisted by a sub-committee of other educationists. It is hoped to develop a really comprehensive scheme, which shall minimise as much as possible the break in studies and the loss of skill caused by the calling up of the whole youth of the nation.

THE KING'S FUND FOR THE DISABLED.—The trustees of this fund, for whom the Minister of Pensions, Mr. Hodge, signs as chairman, make an urgent appeal for subscriptions "which will help to find a new place in civil life for officers and men of His Majesty's Forces disabled in the War, and for the widows and children of officers and men who have given their lives for us." It is pointed out that, apart from a State pension scale, there is a great human field which the King's Fund can cover. The amount aimed at is £3,000,000. His Majesty has not only given his name to this "monument of gratitude," but subscribed £78,000. Mr. Hodge says: "We are receiving 600 applications a week; 2,500 cases have been dealt with thus far. Where the officer or man has been trained by the Ministry of Pensions, or where there is a business given up for war service which he can restart, an adequate grant can be made." Men and women have been helped to establish themselves in the following and other businesses: boot repairers, greengrocers, drapers, clothiers, tailors, cycle repairers, tobacconists, newsagents, carpenters, plumbers, allotment holders, builders, poultry farmers, pig breeders, taxi drivers (to buy cab on hire purchase), hawkers, costermongers, window cleaners, etc. Grants have also been made to help consumptives to go overseas for health purposes. It is desirable to give more than the £25 hitherto regarded as a maximum grant in certain specified cases where it is deemed necessary or advisable. Contributions should be sent to the King's Fund for the Disabled, Westminster House, Millbank, S.W. (1) All cheques and postal orders should be crossed.

JAPANESE ELECTRICAL INDUSTRIES.—The *Board of Trade Journal* announces that Japanese electrical engineers have an ambitious scheme to replace the German electricians in the market in China, and, after the war, to contest that big commercial theatre with American and British competitors. Recently a party of Chinese business men and journalists arrived in Tokio in compliance with an invitation from the organisers of the Electrical Exhibition which took place at Uyeno Park. Japanese electrical industries have so far supplied China with electric lamps, wires and cables through their establishments at Shanghai. One of the latest of them has also the supply of these goods in sight. But the opportunity offered by the German withdrawal, and the stoppage of supplies of electrical machines from Great Britain and America is now being seized, and in the Electrical Exhibition the preparedness of Japanese engineers in this new campaign was clearly depicted. According to the latest official census the capital invested in the mechanical industry in Japan is estimated at 180,000,000 yen (yen = 2*s.* 0½*d.* at par), which is principally laid in machine shops and rolling-stock works. The total estimated value of turnovers is 300,000,000 yen a year, and no small part of the figure is in machines. Power supply and electric transportation systems number more than 700, and the capital invested amounts to 600,000,000 yen. The power generated is above 1,000,000 h.p., and the aggregate length of the railways upwards of 1,000 miles. The export from Japan of electrical lamps and apparatus is estimated at 7,300,000 yen a year; Japan was dependent entirely on foreign supplies several years ago. At the Tokio Exhibition almost all departments of the electrical industry were covered, and the exhibitors numbered 227.

PROCEEDINGS OF THE SOCIETY.

SPECIAL LECTURES.

THE FREEDOM OF THE SEAS.

By Gerard Fiennes.

Lecture I.—Delivered May 2nd, 1918.

In the beginning the seas were free—free from every oppressive keel. Man, so far as we know his history, wandered a happy nomad on plains where he had plenty of elbow-room, where his flocks and herds could graze in peace, and where the only fear of contention was the chance of some dispute with a fellow-shepherd for the right to use a well. Probably he early discovered that a tree trunk or a blown bladder would support him in moist safety on the bosom of the rivers near which he made his home, and, when his wants began to expand, that the river itself was a convenient inclined plane up, or down, which he could transport the wherewithal to satisfy his needs. The estuary gave him fish, and the islands lifting in the distance tempted him to adventure. But the knowledge of the lands and tribes which lay beyond was yet to come.

With growing density of population, however, and the spread of intercourse and knowledge, there came the need for law—the definition and the limitation of primitive right, and the curtailment of personal liberty for the common good. Law demands a policeman, and the strongest or the most cunning was usually accepted as the policeman-in-chief—call him king or Pharaoh. His law ran as far as his arm could reach, and that was to low-water mark on the shore. Beyond that lay the sea, free and lawless, and to it went those who either were lawless, or who would be free.

Greatly daring, they ventured forth, and found what there was to find on the other side. After these first adventurers went the merchant in search of gain. Phœnicians and Greeks who, driven by different causes, took to seafaring at much the same time, met first in Cyprus and entered into relations of mutual trade. They established some sort of law between themselves—for instance, a broken potsherd entitled the holder of either half to hospitality in the land of the other. The stranger had need of the protection of the law on land. But on the sea itself there was perfect freedom and no law. Greeks and Phœnicians each founded colonies—Tarshish, Gadeira in Spain, for instance, and Massalia, where Marseilles now stands. Here the seafaring races first came into conflict. While they traded peacefully at home they fought each other for their colonies, and, naturally, on the sea routes which led thereto. The sea was free—but especially to the stronger. In these contests the Phœnicians, as a rule, prevailed, and became the sea-mercenaries, first of the Persian Empire and then of Alexander the Great.

The seas, then, were free in peace, though, being without law, the peace which prevailed upon them was that of Hounslow Heath while Dick Turpin and his tribe flourished. The freedom of the seas was the freedom of the malefactor as much as of the honest trader. In war the seas were no more free than they have been at any other time in history. The Athenians, under the counsel of Sophocles, cut off the wheat-ships which brought food to the Spartans in the early part of the Peloponnesian War; the Romans held the shortest line of Hannibal's communications with Italy during the Second Punic War; Cæsar fought Antony for the dominion of the world by sea at Actium in the battle-haunted waters where sea-power also decided the fate of East and West at Salamis and Lepanto. It was left to the German of to-day to enunciate the doctrine that the freedom of the seas involves a free path for ambitious

militarism. If this be admitted, the freedom of the seas spells the enslavement of the land.

Passing the early times in hasty review, we come to the age of the Vikings, by no means to be confounded with the Anglo-Saxon settlers on our shores. The Vikings deserved the name of pirates—for a pirate is but an adventurer; and, in later times, such adventurers were even dignified by the qualifying term of "gentleman." The Vikings were gentlemen, though their methods were summary. They enjoyed the freedom of the sea, for there was none to dispute it with them in the northern tracts wherein they sailed. They had their differences with each other; but, although Viking fleets would sometimes fight each other out of sheer sportiveness, these occurred when they harried each other's homesteads, and concerned the land rather than the sea. Alfred, however, disputed their title to that unhampered access to alien shores in which they anticipated the German conceptions of true freedom, and in doing so he laid the foundations of that theory of defence on which the safety of these realms has ever since depended.

Up to this point there has been no trace of a theory of law governing the use of the sea highway. It was the common pathway of the adventurous. Those who used it went armed, though, be it noted, the arms they carried were the arms of the men on board, not of the ship herself. Piracy consisted not in the capture of ships, but in forays on the shore. The daring few alone used the sea, and the only law was the discipline of the ship herself. She was a floating State, a province—as she still is—of the country to which she belonged. This of all the northern seas. The Mediterranean was now a Roman lake, and the oceans beyond were practically unknown to man.

With the break-up of the Roman Empire, however, a different state of things arose. The nations using the sea multiplied. The free use of the great highway was no longer undisputed. There was still no law, and now war rather than peace became the rule—war, even though the countries were at peace with one another. The trading vessel at sea offered a better prize to the pirate than any he could gain from forays on the coasts of the more highly organised States. But as yet piracy was hardly deemed discreditable, and even the vessels of the Cinque Ports, between the calls upon them for the King's service, are believed to have indulged in irregular practices. In the reign of Richard II. valiant John Philpot, Lord Mayor of London, himself equipped and commanded a fleet wherewith he fought and captured a famous Scottish pirate, one John Mercer—for, said he, "We must catch the wasp that stings us and do our best to smoke his kindred from the nest. The nobles who should defend us are laggers and excuse-makers. They do not feel the prick of this thorn as we merchants do, and so they neglect to pull it out. But, an they like it or not, the thorn shall out, and, if they will not attempt it, why, we must."

The history of piracy in the Early and Middle Ages is exceedingly interesting. Kings desirous of sea-power were wont to use pirates as their captains—for pirates, above all others, had the habits of the sea. Ere the Romans left Britain they hired one Carausius, and appointed him Count of the Saxon shore, to ward off the attacks of the Vikings. Carausius seized his opportunity to assume the Imperial purple, and very fine gold coins of his are in existence. He has been claimed as the first of the British sea kings, and elevated to a pedestal as the father of the Navy. But this is romance. He was not a Briton at all; he came from the estuary of the Scheldt.

The great Alfred is also said to have hired pirates to assist his infant fleet. Eustace the Monk, of whom presently, was likewise a pirate, hired to command the fleet of the King of France. Coming down to the reign of Henry VIII. we again find a pirate in command of the French fleet—one Prégeant, called by the English "Prior John." He was the hero of the strange episode in which the English admiral, Sir Edward Howard, lost his life in Brest Harbour. The story is told by Mr. Ernest Law in his book, "England's First Great War Minister."

In such strange ways was the "Freedom of the Seas" maintained till comparatively recent times. Seafaring was a profession almost divorced from life ashore.

The freedom of the sea, however, was "impeached," to use the Elizabethan term, only by pirates in time of peace, while in time of war sea-fighting was between what we may call the armed transports carrying armies from shore to shore—for example, the sea battle between Hubert De Burgh and Eustace the Monk off Dungeness, the Battle of Sluys, and the Battle of Espagnols-sur-Mer, fought off Winchelsea by King Edward III.—at least, so far as the Channel and North Sea were concerned. In the Mediterranean it was different. As against pirates we begin to get the faint

glimmerings of a law at sea. Edward III., after the Battle of Sluys, claimed the title of the King of the Seas, and first exacted the salute from all foreigners, which afterwards led to the first Dutch War. As a price of their acquiescence in this acknowledgment of sovereignty the Hanseatic merchants, Flemings and others, who used the seas for trade, intimated to him that they looked to him to keep a passage for their ships free from the depredations of pirates. "The Sovereignty of the Seas" was thus made to carry with it the first obligation of all sovereignty—the preservation of law and order.

In the early fourteenth century the Hansa rose to power in the Baltic and North Sea. According to the custom of the Phœnicians in early times, and of the Dutch and English afterwards, the Hanseatic merchants established trading houses in the countries with which they carried on commerce. Here the goods were collected, and hence they were borne in the ships of the League. Their great staple, however, was the herring, at that time so plentiful in the waters of the Sound that the shoals were said to have lifted boats out of the water. The Hansa claimed a monopoly, which the Danes disputed, and this led to a confused series of wars which were ended by the Peace of Stralsund in 1370. Here we find the principle of the freedom of the seas distinctly challenged, and the principle that the Baltic should be *mare clausum* of the Germans asserted. It is noteworthy that the Hansa laid down the principle that "enemy ships make enemy goods and enemy goods make enemy ships"—which is the precise opposite of the principle which the modern German would fain establish.

After the Peace of Stralsund, the Hanseatic merchants—or some of them—took to unabashed piracy. They founded societies, known as "The Equal Sharers" or "The Victualling Brothers," and their dictum was turned to their own confusion, for a large Hanseatic fleet, returning from the Bay of Biscay, was captured by the English; while, on another occasion, no fewer than 108 ships were seized by a fleet fitted out by the east coast ports. This latter event occurred in 1451. The practice of seizing merchantmen as an act of belligerency was thus established. Belligerency, moreover, became the normal condition at sea.

In the Mediterranean the freedom of the seas was altogether lost between the eleventh and the sixteenth centuries or later. For this there were three reasons: the rivalries between the three republics of Venice, Genoa, and Pisa for the monopoly of the trade of the Levant; the Crusades, which called upon the resources of the three republics for sea-transport; and the establishment of the Turkish power, followed by the rise of the pirate Barbary States of Tunis, Tripoli, and Algiers. The Venetians, indeed, claimed the Adriatic for their own, and the Genoese the Tyrrhenian Sea. Here we find an application of the doctrine of the *mare clausum*. But once the foot of Italy was cleared, the open Mediterranean was held *mare liberum*, subject only to the monopolies claimed in Levantine ports. It is impossible to do more than touch on this subject. The history is confused; but, in brief, it may be said that the Middle Sea was a theatre of rivalries, and that, if one argosy of a fleet got safe to port, the merchant was a lucky man. The case of Antonio, as given by Shakespeare in "The Merchant of Venice," was no exceptional one. Venice, however, prospered at least in the earlier days owing to the foresight of the Doges in maintaining a war navy to protect her merchantmen. The seas were, indeed, free—as free as the freebooter!

To give an instance of the looseness with which obligations on land sat upon those who followed the sea. In 1099, Baldwin, King of Jerusalem, applied to Venice for assistance, and the Doge, Vitali Michiel, got ready an expedition which sailed for Rhodes, where it wintered. A bloody quarrel immediately broke out between the Venetians and the Pisans. The Venetians were victorious, but restored to the Pisans all the ships and prisoners they had taken, on condition that the latter pledged themselves to trade no more with the Levant This done, the armaments of the two Christian Republics sailed off amicably together to the Holy War. The merchant princes of Venice could be trusted to remember that "business is business." The Venetians lived by trade; and successful trade at this time and years later was thought to require, not only safe communications by sea—which it unquestionably does—but also monopoly in the trading marts, a doctrine not overthrown until British supremacy was established and British policy showed the more excellent way.

By the middle of the fifteenth century affairs had reached an *impasse*. Freedom without law had borne its inevitable fruit. It had resulted in the liberty of the strongest to work his will: the liberty of the wolf among lambs, or of a

dogfish in a shoal of herrings. The first attempt to evolve order out of this chaos by imposing law at sea was made by that model ecclesiastic, Pope Alexander VI. Bartholomew Diaz sailed round the Cape of Good Hope in 1486, and in 1492 Columbus, as emissary of Ferdinand and Isabella of Spain, discovered the Bahamas. In order that the scandal of the Crusades might not be repeated, and that Christians might not fight each other for the privilege of bringing the heathen into the bosom of Holy Church and the gold of the heathen into the coffers of their monarchs, Alexander magnificently divided the Atlantic by a line down the centre. All to the east (and Brazil to the west) was the sphere of Portugal; all to the west (with the exception of Brazil) was the sphere of Spain. For the first time then the ocean acknowledged an owner—so far as a Papal Bull could bring such a thing about. The Powers of Christendom, to the extent that they were interested in the matter, bowed to the decision of the Sovereign Pontiff. Five years later Henry VII. issued a remarkable licence to John Cabot and his sons. It ran:—

"Henry, by the Grace of God King of England and France, Lord of Ireland, to our trusty and well-beloved subjects, Greeting:

"Be it known to all that We have given and granted, and by these presents do give and grant, to our well-beloved John Cabot, citizen of Venice; to Lewis, Sebastian and Sanctius, sons of the said John, and to their heirs and deputies, full and free authority, leave and power to sail to all ports, countries and seas of the East, of the West and of the North, under our banners and ensigns, with five ships of whatsoever burthen and quality they shall choose, and as many marines and men as they will take with them in the ships on their own proper costs and charges, to look out, find and discover whatsoever isles, countries, regions or possessions of the Heathens or Infidels, wheresoever they be, and in what parts soever of the world, which before this time hath not been known to all Christians."

Notice how carefully compliance with the Bull of Pope Alexander VI. is safeguarded. The Cabots are to sail north, east or west, but not south; they are only to look out, find, and discover those "isles, countries, regions, or possessions" of the heathen which were not at that time known to Christians. The purpose of the Cabots was to discover the north-west passage to India, as Willoughby afterwards set out to discover the north-east. It was obviously intended that they should cease their endeavours at the point where they came in contact with Spaniards or Portuguese who had reached the same districts from the south.

Then came a change. Henry's son cut loose from Rome, and the adventurers of England added to the joy of "singeing the King of Spain's beard" the duty of striking a blow at the monopoly granted by the Papacy in the name of the Reformation. Time forbids that I should re-tell the story of Drake and the other great sea-captains of Elizabeth's time. But it is of importance to recall an incident. Mendoza, the Spanish Ambassador, protested to the Queen against Drake's impertinence in daring to sail in the Spanish Main. Said Queen Elizabeth in reply: "Tell your Royal master that a title to the ocean cannot belong to any people or private persons, inasmuch as neither nature nor public use or custom permitteth any possession thereof." The freedom of the seas was thus asserted. They could belong to none, and none could grant monopoly of their use. But that this dictum did not extend to a claim that all should use the sea for every purpose, whether for peace or war, is shown by the action of Elizabeth's captains, who seized sixty ships of the Hansa in the Tagus harbour during the Armada campaign, on the ground that they were trading with the enemy. To use the words of the Book of Common Prayer, the sea was free, but only to those who were upon "their lawful occasions." Whether the occasions of Drake and Hawkins were "lawful" is, of course, a point about which it was possible to hold two opinions, and Mendoza chose his ground badly when he protested against Drake's presence in the Spanish Main rather than upon his proceedings there—which might have proved less easy to justify.

After the spacious times of Elizabeth, many a prime English seaman was discharged and took to piracy. Some even entered the service of the Barbary States and became "Sallee Rovers." Perhaps they but little bettered the example of their captains. At any rate, it may be said that the English, by overthrowing the tyranny of the Spaniard, had upset the law established by Alexander VI., and, in a time of temporary weakness, reaped the consequences. James I. offered pardon to any who would abandon his ways. "I have no intention of obeying the orders of our King, when I am, in a way, a king myself," said haughty John Exton, one of the most notorious of the pirates. James was fain to let the Dutch root out the buccaneers, even from Irish harbours. There was as yet no Power strong

enough to police the seas in the interests of humanity, and freedom still wore the cloak of maliciousness.

The curious topsy-turvydom of the sea affair in the reigns of the late Tudors and early Stuarts is seen by the position of the Dutch. After Amsterdam was "founded upon the herring," for eighty years the people of Holland were engaged in a bitter struggle with their masters, the Spaniards. But the latter were also in conflict with the English, and trade from the Americas in Spanish ships was unsafe. The Dutch and English, though there was no formal bond, were fighting in the same cause, and Dutch ships were immune from English capture. Thus it came about that the very gold for the King of Spain's treasury was brought in Dutch ships. The burghers of Holland grew rich. They established themselves also in the Portuguese trade with the East, thus annulling the Bull of Alexander VI., and became the toughest rivals the English have ever met at sea. The ostensible cause of the series of struggles which lasted through the times of the Commonwealth and of King Charles II. need not be traced. The underlying cause is summed up in the blunt words of Monck: "What matters this or that reason? What we want is more of the trade that the Dutch now have." The era of trade wars had now definitely begun. But the term needs explanation. It was not that the right of any nation to trade by sea was denied, except in so far as the Spaniards denied it in the Spanish Main, but that each nation possessing oversea colonies desired to preserve the monopoly to itself, and, further, to secure the valuable position of "the waggoners of the world." The Navigation Acts of Cromwell and Charles II. were framed to secure the first object, and they were the real, if not the ostensible, cause of Dutch hostility. The determination of Britain that British colonial goods should only be conveyed in British bottoms, manned by two-thirds British crews, struck directly at the position of the Dutch as "waggoners." Britain prevailed by reason of her geographical position, and the circumscription of Dutch sea-power destroyed their reputation as safe "waggoners." This, with the pressure of continental foes on the land side, reduced Holland from her position of supremacy, though her maritime position continued, and is to this day, respectable.

The freedom of the sea without law, and law on the sea without freedom, had thus both alike failed to secure the right of the nations to the use of the great waters. Monopoly was claimed, and continued to be claimed, though, be it repeated, it was rather monopoly of the ports than of the way thither. That, however, soon passed into the claim to "impeach" the intruder in the easiest way—that is, upon the high seas.

The peaceful administration of Walpole in the reign of George I. was disturbed by the War of Jenkins's Ear. The origin of the dispute is instructive. The British had obtained the right to send a ship a year to trade in the Spanish Main. The licence was liberally construed. It was the custom to load the ship on the side which lay along the quay, and immediately to unload the cargo into the ships which lay on the other side of her. Other illegal practices prevailed, with the connivance of the Spanish colonists, who, except for the contraband traffic, were bound by the Spanish system which permitted them only to ship goods to a single port in Spain. Preventive measures in the ports would, obviously, have been useless, in face of the sympathy of the inhabitants with the *contrabandistas*. The Spanish *garda costas*, therefore, were in the habit of capturing what ships they could on the high seas. Among others, they captured Mr. Jenkins, and, as he alleged, cut off his ear, sending him with a message that if his Royal master ventured into the Spanish Main they would serve him the same. Jenkins pleaded his cause at the Bar of the House of Commons, and his story set England aflame, especially his answer to the question what he did under the distressing circumstances which beset him: "I commended my soul to God and my cause to my country." Britain threatened war on Spain. The struggle was speedily merged in the greater conflict of the Austrian Succession. But the people felt that they were fighting for the old cause of the freedom of the seas. Whether this was, at that time, meant to include the freedom of the ports must remain doubtful.

The next eighty years were years of almost continual war; indeed, the war was continuous on the sea, though there were short and troubled intervals of peace on land. France and Britain, with Spain as an intervener, fought for the sovereignty of America and India. The war in the distant possessions, especially in India, went on even while the home countries were nominally at peace, and the trade was held liable to capture unless it could defend itself. The mercantile system was at its height. The monopoly of each country with its colonies was jealously guarded, and, as a consequence, smuggling, with

the connivance of the colonists, was rampant. This was especially the case with the West Indian Islands after the independence of the United States was acknowledged. The ex-colonists did not easily reconcile themselves to exclusion from the privileges they had previously enjoyed as subjects of King George, and Nelson's early services as a captain were largely spent in endeavouring to suppress the illegal trade which sprang up.

Under these circumstances, it cannot be alleged that the freedom of the seas was maintained. Each country, claiming that its ships were part of its territory, applied its municipal law. Thus, towards the end of the eighteenth century, it was established that a slave was free, once on board a British ship, since Lord Mansfield, in the year 1772, in the case of the negro Somerset had decided that no man could be a slave on British soil—and this while the Assiento clause of the Treaty of Utrecht, giving Britain the monopoly in the slave trade between Africa and the New World was still in force. One interesting light is shed on the ideas which prevailed by the legal fiction that all crimes or causes which arose on the high seas were committed or arose "in the County of Middlesex."*

"Freedom of the seas," then, in time of nominal peace, was the freedom of the stronger only. There was latent war; there were countless regulations against smuggling which led to captures, and trial according to the municipal law of the captor; and there was the piracy of the Barbary States and of individual adventurers which the nations made no concerted effort to suppress. The idea of free and regulated intercourse of one nation with another hardly existed. Each, in fact, claimed a monopoly along its own trade-routes, and every other nation contested it.

In time of war a code of law or custom was maintained. At first it may be doubted whether it was generally held that enemy goods in neutral bottoms were capturable. But when the French who, up to then, had been stubborn upholders of the mercantile system, began to ship the produce of their colonies to France in neutral bottoms, then the British were quick to maintain that sauce for the peace goose was sauce for the war gander, and that, as the goods would have been unquestionably capturable in French ships, they could not be rendered immune by transfer to neutral bottoms. Hence arose the famous "Rule of 1756," which is the basis of all our Orders in Council and Prize Court regulations. This Rule, when applied in the War of Independence, gave rise to the first armed neutrality of the northern Powers, and brought in the Dutch against us. It has had momentous consequences in all naval history since. Re-introduced, with modifications, during the Napoleonic wars, it was extended so as to ensure that every neutral ship plying to a European port under the control of Napoleon, should first pay tribute to Great Britain. Napoleon, on the other hand, tried to exclude all goods which had a British taint from the Continent, but with small success. Be it noted, that the principle of mercantile blockade at that era was the precise reverse of that which obtains in the present war. The Continent tried to ruin Britain economically by shutting out her goods; Britain tried, and successfully, to get all the goods she wished into the ports of the Continent, both her own, and those of foreign States which had paid her a toll.

After 1815 Britain was unquestionably supreme at sea, and she set about her great work as law-giver and policeman. She was left with an unrivalled chain of maritime stations in her hands, and these she greatly increased during the years of European peace. The age of steam helped her, since she possessed almost a monopoly of steam coal. Other maritime nations became dependent upon her, and she opened her ports freely to them. She sold them ships, and she employed their subjects as crews for her own. Not only so, but she also used her naval strength and freely spent her wealth to suppress piracy and the slave trade; to survey, chart, light, and buoy the fairways of the world. Freedom and law were at last met together, under the ægis of the one State which possessed supreme sea-power, and used it for the good of the world. The small maritime States, Holland, Norway, Sweden, Denmark, and Greece, flourished under the *Pax Britannica*. They needed no navies to protect their commerce; such protection as was necessary was at our charge. There was no altruism in this; it served our ends.

Turning from peace to war, it was our habit throughout the nineteenth century to regard ourselves not as a belligerent, but as a neutral with the greatest maritime interests, and the agreements we signed, such as the Declaration of Paris, 1856, had our interests as a neutral in view. Free ships were to make free goods; neutral goods were not to be capturable in

* This "floating island" theory is strenuously denied by many jurists, who point out that Statute Law does not run at sea. Perhaps it should be said that the Common Law of each country prevails until it is suspended by international convention or agreement. That is to say, that when a law of the sea is required and there is no law, the most convenient substitute is applied.

enemy ships; blockade to be valid must be effective; privateering is, and remains, abolished—and so forth. The petty squabbles of lesser mortals were not to disturb our Olympian aloofness.

Then came the war, and the freedom of the seas which we had established and preserved was challenged by a nation of inferior sea-power in a novel way. The phrase was adopted as a catchword by our enemy, who, at the same time, was violating the thing itself in every conceivable way against both the law and comity of nations. What the Germans mean by the freedom of the seas is obscure. But the end and purpose of the German demand seems to be that the maritime nations shall be left helpless in the clutches of an ambitious land Power. Not only is a Continental belligerent to receive all the comfort and succour which can be sent from oversea, but he is to have the right also to send his transports unchallenged until they reach low-water mark on the coasts of his enemy. The barrier between free mankind and tyranny is to be done away; the sea is no more to be "as a moat defensive of a house" behind which—or, rather, behind the fleets which guard it—nations may develop their life free from the burden of conscript service, but is to be a highway for the passage of armies unscathed by the resistance which would meet them on shore, or which, at present, would make their passage by sea perilous.

Germany makes little secret of the fact that what she seeks is freedom of the seas in time of war, in order that the greatest obstacle to her lust of world-domination may be removed. For peaceful commerce the seas are free, thanks chiefly to the work of Britain. Germany, who has proved that she possesses the morals of a pirate, seeks to re-establish in an aggravated form the freedom of the malefactor.

Whether, in some future blissful condition of the world's politics, there may emerge a Law of Nations extending to the sea as well as to the land, the future must decide. Up to the present, law has been coincident with territorial possession, and the true freedom which goes with law-freedom—that is, for strong and weak, great and small alike—has only been secured when one country was strong enough to make its ideals prevail at sea. In any other sense, we shall only secure "Freedom of the Sea" when the federation of the world is an accomplished fact. And then the era of war will be at an end. In peace, no greater freedom is possible than was maintained during the reign of Britain between 1815 and 1914.

INDUSTRIAL DEVELOPMENT IN INDIA DURING THE WAR.*

By D. T. Chadwick, I.C.S.,
Indian Trade Commissioner.

(*Continued from p.* 658.)

In the range of metals, the importance of the Indian deposits of mica, wolfram, and chrome are well known, and the workings of these have all been extended. The opening of the large Bawdwin deposits by the Burma Corporation should supply large quantities of lead, silver, zinc concentrates, and copper. The output of this Burma pig-lead, which is of high grade, already equals approximately India's pre-war needs. Tin deposits have very recently been reported from the Thaton district, near Amherst, in Burma. With the iron and coal resources of India now being actively opened out, and with non-ferrous minerals also being commercially worked, there are better prospects than have hitherto existed of India having available those metallurgical resources which are vital to all industrial development, and which hitherto she has lacked. The manufacture of the alloys of iron has commenced, with that of ferro-manganese. A set of electric furnaces is also being erected at Sakchi, primarily for refined steel for springs, tools and other purposes, but should occasion demand, these also will be devoted to making other ferro alloys, *e.g.* ferro-chrome, ferro-tungsten, etc. Concurrently and inevitably with these developments and needs engineering shops in India have been enlarged and new ones started. But they, and in fact practically all these industrial efforts, have naturally had to contend with the greatest difficulties in obtaining machinery and equipment.

Furnaces, works and factories cannot, however, be built cheaply without local supplies of structural and refractory materials. Structural steel is now available in considerable quantity, and will be forthcoming in the future still more largely; whilst the capacity of works producing cement of British standard quality has, during the war, increased from about 5,000 tons to some 70,000 tons, and further developments are certain. Among refractory materials a beginning has been made with silica bricks claimed to be equal in quality to those of England or Japan, and large quantities of these will be needed. The magnesite deposits in the Madras Presidency are of a high purity. The manufacture of

* Delivered at the British Scientific Products Exhibition, September 3rd, 1918.

magnesite bricks is thus sure to follow. Though Indian asbestos appears totally unfit for textile purposes where flexibility is of great account, it may yet prove suitable for boiler-lagging and fire-proof compositions. Thus some of the first steps for developing locally the metallic resources of the country have been taken. But this is an age not of iron alone, but of iron and chemistry. And perhaps it is in regard to the supply of some of the primary chemicals and in the solving of chemical problems connected with Indian industry that the greatest difficulties for advancement lie. One of the first difficulties is to ensure an adequate supply of cheap sulphuric acid, of which at present the local production is small, though this should become possible if the Burma zinc concentrates are smelted in the Bengal Presidency.

Another basal chemical which is not yet produced satisfactorily locally is caustic soda. Among ammonium salts, sulphate of ammonia is obtained at present chiefly as a by-product from the coke ovens. When one turns to the large number of derivatives from coal tar, one is met by the unfortunate fact that the yield of tar and acid constituents from Indian coal is as a rule low, only being 2·1 per cent. as compared with 4 per cent. in Great Britain. The possibility of developing local resources for aluminium and calcium carbide, cyanamide, etc., turns on the supply of cheap electric power from the waterfalls of India. Electric power has already been supplied successfully to industry in India on a limited scale. The two best known cases are those at the Cauvery Falls in Mysore, chiefly to supply power to the Kolar goldfields, and the more recent Tata hydro-electric scheme for supplying Bombay. In the first of these the capacity of the power-house at present is 22,650 electric horse-power, and in the second 100,000. Both are being extended. But for these basal chemical and metallurgical industries still cheaper sources of power are required, and the Tata interests have investigated a proposal for throwing a dam across the Koyna River in the Western Ghats, whence 300,000 horse-power per hour will be obtainable throughout the year. It is certain that the possibilities of the use of water-power in India for applying electrical energy have by no means been exhausted, and with their further exploitation a development of some of the industries based on a supply of cheap electric power can be expected. Apart, however, from these chemical industries, the inception of which depends on the existence of cheap power, there is a large number of chemical problems associated with industry in India waiting solution. One of the activities of the Munitions Board has been to "mobilise" the chemists at present in India, and allocate to them specific problems for solution. Hitherto, except in a few cases, chemists in India have been mostly employed in the educational departments scattered throughout the colleges of India, and, generally speaking, have not been in touch with industrial problems. Full advantage has thus not always been taken of their knowledge and training. In this respect India does not stand alone. This knowledge and talent is now being utilised. In every case they have to work with and on substances available in India. A few of the items of research allotted to different chemists may be cited as indicative of the class of work undertaken. Such are colloidal medicinal preparations, the causes which render bleaching powder unstable in hot climates, the preparation of suitable chromate by extraction from chrome iron ore without the use of caustic soda or sodium carbonate, the fire-proofing of gunny cloth, the purification of nim, gingelly and Indian fish oils, indigenous sources of tartaric acid, the refining of waste copper, the refining and preparation of several of the essential oils, varnishes, methods to prevent the deterioration of turpentine oil under storage, the dyeing of skins, furs and tussar silk, the isolation and cultivation of the specific yeast associated with mahua flowers, etc., as well as the manufacture of acetone by the fermentation process for which at present the most satisfactory material from a technical and economic point of view appears to be cholam or jawari—the larger millet. There is, however, one product associated with a historical and romantic Indian industry which is on exhibition in this building—in Section XII.—which illustrates the co-operation of planters, business houses, Government, and scientists in India and England. I refer to indigo—an article which appears in the earliest shipping lists of the old East India Company, away back in the seventeenth century. This is no time to dwell on the serious competition from which indigo has suffered. The war caused a great and sudden revival of interest in it. This opportunity has not been treated as a mere chance for recovering some earlier losses; it has also been utilised for serious organisation and

definite research work, in which the Behar planters, the Government of India, and a strong scientific and business committee in England, in which Professor Armstrong takes an active part, are all co-operating with the double object of increasing the outturn of indigo per acre, and also of putting the final product on the market in the form of standardised paste. Work on all crops takes time. The seasons are inexorable; but progress has been made, and none except perhaps a most aggressive chemist, if such there be, will fail to wish success to these efforts to preserve for the world the finest of all vegetable dyes, and one which at its best is generally admitted to possess certain qualities lacking in synthetic products.

It may seem strange, when speaking of a land of rice and wheat, to allude to new food-stuffs. But the exigencies of war have turned attention in India, as elsewhere, to food. Samples of malted foods from Indian cereals have been prepared, and from Bombay comes the report of a purified ground-nut flour of considerable nutritive value, and not dissimilar from the cotton-seed flour which in this country has been recommended as a suitable diluent for wheat. Indications seem to point to the likelihood of testing thoroughly the possibility of jam-making in certain parts of India.

In this brief summary an effort has been made to sketch some of the main outlines of the new industrial developments in India during the later years of the war. The largest contributions in material goods have naturally been made by the large and varied textile industries extending over a wide range of articles, from khaki cloth and turbans to blankets and coir screening. And to supplement the efforts of the mills, many of the hand-loom weavers have been employed on tasks within their capacity. The feasibility of employing the old indigenous craftsmen of India has thus not been neglected, though obviously it is more difficult to ensure working to specification by them than by the large mills. The mere enumeration of the articles made in these various branches of textiles would exhaust all the time allotted for this lecture. So it has been deemed preferable to concentrate attention on what are, perhaps, the less widely-known industrial efforts in India, and to mention some of the difficulties they have had to meet. Frequently work has had to be done with makeshift apparatus and machinery, and it must not be supposed that every effort mentioned in this lecture will ultimately blossom into a large successful industry. Some wreckage there is bound to be when the period of transition comes. In endeavouring to summarise in thirty minutes a wide field of endeavour and activity, it is difficult to avoid causing, perhaps, a too roseate impression of progress. Anyone who knows India realises that there are difficulties ahead when full competition again becomes operative, but some solid progress has been made; and I hope that this brief sketch does show that there is a wakening spirit abroad to industrial possibilities in India, and also that there is a strong hope of effectively widening the basis of industrial employment in India. Most industries are in some ways interdependent, and in diversity is to be found strength. Such diversity India, before the war, lacked. The attaining of it in war time when machinery was especially difficult and costly to obtain, and finance always a problem, has been and remains a difficult task; but it was the stress of war which showed clearly the vital need, and also gave the stimulus to joint and organised effort, and which has also shown that with well-established, well-managed industries, India can be an added source of strength to the Empire in general.

One of the greatest needs of the immediate future is for more organised practical scientific research into the industrial resources of India, both in forestry, mineralogy, hydro-electricity, and in industries themselves. In the more thoughtful circles in India this is generally recognised.

In spite of this progress, which all good wishers of India desire to see maintained and increased, India will continue for long to be mainly an agricultural country, and the change to industrial pursuits will only affect part of her population, of which at present a disproportionate section are still dependent on agriculture. Some Indian industries have often been criticised on the ground that employers have paid insufficient attention to the conditions under which the workmen labour and live. This must not be accepted too sweepingly. The more far-seeing business leaders of all communities are interesting themselves in welfare work, in schools and housing, realising that only by such means can labour become interested in factory work.

This is not a full account of India's economic effort during the war. That obviously cannot be given yet. We do not yet know how far we may be led. In fact, cables received last week

show that another phase is opening, with the orders to make standard cotton cloths at controlled prices—the counterpart in India to the standard suits of England. The repercussions of this war are worldwide, and the problems to which it gives rise present in most countries certain broad lines of similarity, though the conditions in which solutions for such problems have to be sought are widely different. Finally, I wish to repeat and emphasise that this lecture is merely a summary of some of the main lines of Indian industry during the war; it is in no sense an economic survey of India in war time. As in every other country, some have made great profits, other large classes have suffered loss. There is such widespread talk nowadays of raw materials, that the impression easily grows that there must be unlimited markets for all India's raw produce. Such is not the case. Difficulties of transport and finance weigh as heavily on India as on other countries. For instance, the area under cultivation of such a war commodity as jute has decreased since peace time, whilst the markets for some other crops have greatly shrunk. As elsewhere, some in India have lost, some have gained, by the economic dislocation caused by war. How the balance will come out in the end remains for future study to disclose.

INDUSTRIES AFTER THE WAR.

III.—Electrical.

In the general survey with which the weighty report of the Departmental Committee on the electrical trades is introduced, it is urged that the national importance of those trades has never been realised either by the Government or the general public. Through the achievements of Faraday, Wheatstone, Kelvin, Swan, Hopkinson, and many others, Great Britain was first in electrical enterprise, and should have retained her pre-eminence; but manufacturers were hampered while Parliament and local authorities debated how the distribution and use of electricity might be prevented from infringing "conventional conceptions of public privileges and vested interests." Consequently foreign manufacturers were enabled, both in their own and other markets, to gain a hold which they have never lost. The approximate annual value before the war of the total products of electrical plant, mains, and appliances in this country and in Germany is set out in the following table:—

	Great Britain. £	Germany. £
Total electrical products	22,500,000	60,000,000
Exports	7,500,000	15,000,000
Imports	2,933,000	631,000
Consumption of *home-made* machinery . .	15,000,000	45,000,000

Moreover, of the £22,500,000 manufactured here, a large proportion was produced by concerns under foreign control, and in the case of "British" exports a proportion consisted of foreign manufactures reshipped as British goods! Apart from legislative obstacles, Great Britain, it must be remembered, had attained much prosperity and technical efficiency in her use of steam, and therefore her manufacturers had less inducement than their rivals in foreign countries to adopt electrical driving. Another factor retarding our electrical progress has been the "strength of the gas interests." Again, foreign Governments, appreciating the importance of conserving their home markets as a basis for the development of overseas trade, imposed protective duties and exerted influence on State Departments to purchase native goods. An industry cultivated under these and other encouraging conditions has had an immense advantage in international competition. There is, the Committee says, conclusive evidence of the existence of German control over companies ostensibly British, and of that German control being exercised to the detriment of British interests indirectly through companies incorporated in America, Switzerland, and other neutral countries. "At the outbreak of war negotiations were in progress for the acquisition by Germany of financial control in existing companies of the United Kingdom, as well as in the British Dominions and India, which if successfully concluded would have still further restricted the use of British goods in many parts of the Empire."

The scientific replanning of our distribution of energy on which the Committee so strongly insists would, it is calculated, effect a saving of no less than 50 million tons of coal per annum. Witnesses of high authority estimate the loss incurred by the nation through failure to take full advantage of electrical progress at quite £100,000,000 a year.

The larger part of the report is devoted to a careful and detailed examination, from sectional points of view, of the position of the industry. Section I. deals with electricity generation and transmission; Section II. with electric traction; Section III. with manufacturing; Section IV. with the interdependence of manufacture and finance; and Section V. with Imperial control of sources of electrical energy. Respecting the latter, it is suggested that, in particular, India and the self-governing Dominions should take stock of their facilities for generating electricity, whether from water-power, coal, oil, or other sources of energy, and should appreciate their permanent and ever-increasing importance to the Empire.

The Committee concludes by making the following recommendations:—

"(1) Thorough reform of the legislation and conditions under which the generation and distribution of electricity are promoted and administered in this country; and a like reform affecting the promotion, construction, and operation of tramways and light railways. (2) Prohibition of import of

enemy goods for three years after the conclusion of peace, subject to importation under licence in special circumstances after the expiration of the first twelve months. (3) Imposition of import duties sufficiently high to protect effectively the electrical industry. (4) Prevention of the sale in the United Kingdom of any imported electrical goods at prices lower than those current in the country of origin. (5) Recognition of the advantage of combination among manufacturers and official co-operation with such action. (6) Prevention of any concern engaged in the electrical or allied manufacturing industries, if controlled directly or indirectly by enemy capital, from continuing to trade within the Empire, unless it be specially authorised and its constitution made public, and the passing of legislation requiring that not more than 25 per cent. of the capital in any other electrical or allied undertaking shall be held either directly or indirectly by enemy subscribers or their agents. (7) Treatment as enemy products of all goods produced in foreign countries by concerns controlled by enemy capital or under enemy direction. (8) Exclusive acceptance of British tenders by State Departments, public bodies, and companies supplying electrical energy under statutory powers. (9) Adoption by Government Departments and public authorities, so far as is practicable, of standard types and patterns of plant and apparatus. (10) Prohibition of transport discriminations operating to the detriment of British manufacturers, and the provision of improved transport and cargo-handling facilities. (11) Promotion of a better understanding between employers and employed, and the provision of better housing and working conditions. (12) Provision of extended banking facilities, preferably by the establishment of industrial banks, to enable British manufacturers to secure and finance contracts and engineering enterprises. (13) Recognition of the permanent and ever-increasing importance to the Empire of the natural sources of power for the generation of electricity in the British Dominions, and the introduction of safeguards by legislation or otherwise to prevent these national assets from passing into alien hands or under alien control."

The Committee promises a supplementary report dealing, *inter alia*, with education, research, the decimal system, and the consular service.

THE BRITISH SCIENTIFIC PRODUCTS EXHIBITION.

On September 7th the British Scientific Products Exhibition was brought to a close after a run of four weeks. The aim which the promoters had in view was to illustrate, by means of the exhibits, the great advance made in the production of articles of prime importance for the home and foreign markets hitherto obtained from other countries, and the successful realisation of that aim reflects the greatest possible credit upon the Organising Committee. To the British Science Guild belongs the honour of having promoted the Exhibition, and of assuming the financial responsibility. It is generally supposed that the project was in some way supported by the Government. That is not the case, for, apart from the remarkable display of the Air Ministry, and some exhibits by the Munitions Inventions Department, and some other optical departments, the authorities have neither supported nor assisted the Committee in any way, except that the Board of Trade loaned some show-cases. An honourable exception can be made in the case of the leading officials of certain departments. The Exhibition was visited by large numbers of the public, who, by their intelligent interest in the appliances shown, completely disposed of the idea that they are indifferent to scientific work and its possible industrial results. If the British Science Guild carries out its intention of holding an annual exhibition of British progress in science and invention, it will be performing a service of the highest national importance.

In the limited space available it is impossible to review the exhibits in detail; for those who were unable to visit King's College there is still available the excellent descriptive catalogue,* with its useful articles on recent developments, which will serve as a reliable guide to the progress achieved in scientific industries since the outbreak of the war. The exhibits covered a wide range, and included chemical products and processes, physical and electrical appliances, optical apparatus, measuring and mechanical instruments, surgical, bacteriological, and pathological appliances, including X-ray apparatus, etc. In practically all the sections the degree of progress indicated by the exhibits was surprisingly great, and even where no striking development has occurred in the way of new invention, there was noticeable a marked general improvement in apparatus constructed on the recognised lines of pre-war days.

Interest naturally centred round those exhibits associated with aircraft production. Here the developments and the differences between present-day aeroplanes and those of a few years ago were clearly marked. Modern spars, for instance, are much stronger for a given weight, engines have been developed, both as regards the material and construction, to the extent of reducing their weight by more than one-half, whilst the size and power have grown enormously, and are still making advances. The materials which have been produced since the outbreak of the war, and of which aircraft constructors have been able to avail themselves, have made it possible for the greater part of an aero-engine to be made of light alloys. In non-metallic materials the investigation of timber has led to some interesting results. With regard to the many fittings which go to make up the complete aeroplane, one item of outstanding interest is the magneto. Before the war the Germans had practically a monopoly in the

* London: The British Science Guild, 199, Piccadilly, W. (1) pp. 268. 2s. 6d. net.

manufacture of this article both for car and aeroplane use, the Bosch magneto undoubtedly being the most popular throughout the world. The war has changed that, and the British manufacturers have seen to it that the home-built magnetos are worthy of their name. This is a very striking instance, and is a most promising augury of future trade. There are now nine British firms engaged in this work, with the result that during the past four years 300,000 magnetos have been manufactured for war service alone. What is equally important is that the home-made magneto is now as good as, or even superior to, the previously imported Bosch machine. The development of dope for the fabric of aeroplanes has been the subject of many investigations, and the planes of the present-day machine are rendered taut and weather-proof by means which, though slightly more complicated than varnishing, are many times as efficient. The British dopes consist of a solution of cellulose acetate made from paper or some cheaper form of cellulose, or of gun-cotton dissolved in suitable solvents and diluted in order to reduce the solution to a workable viscosity.

During the war much progress has been made in the manufacture of insulation and of resistance wires, both of which were largely imported from Germany. The same is true of electro-medical apparatus. The examples of these displayed at the Exhibition showed that British manufacturers are capable of supplying our needs and of producing thoroughly sound products. We may pass over the interesting display which furnished a fine example of successful British production on scientific lines of instruments of a high standard, and of the exhibits of refractory materials, in which direction progress has been very marked during the past four years. This is another industry which has been captured from our enemies, and which there is very little likelihood of their ever recovering, for with proper care British manufacturers should be able to maintain their positions in this trade after the war.

Before the outbreak of war lens-grinding machinery was either made by the individual user, or imported from abroad. Now such machinery, at least equal to any imported machines, is available in sufficient variety to cover all the ordinary types of work. At the same time, entirely new methods of working glass have been developed and brought into ordinary use. Some of these methods are particularly well adapted to the manufacture of standardised optical systems. The most striking development in this respect has been the way in which enormous numbers of prism binoculars, sighting and other small telescopes, have been made to meet the demands of the military and naval authorities.

The gradual awakening of the British glass industry since the early days of the war, as revealed by the Exhibition, is a feature which deserves particular mention. The two immediate needs were chemical glass and optical glass. Let it be said, to the credit of British industry, that in regard to optical glass a well-known British firm near Birmingham started the manufacture of this in 1848, and kept it alive at considerable pecuniary sacrifice. Since the outbreak of war its output has increased twenty-fold. Up to nine months after the declaration of war, however, there was no general and active movement among manufacturers to take up new work. Since then steps have been taken to speed up glass manufacture in general, and from the beginning of 1916 the trade has rapidly progressed from a state of dependency or doubt to one of determined optimism. The Exhibition provided some measure of the material results of the re-awakening of the glass industry in this country.

Space does not permit more than a brief reference to the evidence shown at the Exhibition of the development of the dye industry. The outbreak of the war disclosed a dependence on Germany for our supplies of dyes which was little short of appalling. The serious position in which we were placed is evident when we realise that our trade in cotton and woollen goods, as well as the requirements for leather staining and a multiplicity of minor industries, could be carried on only with the aid of these essential materials. Dependent upon the dye industry is that of drugs and fine chemicals, and the evidence of progress in the production of these shown by the exhibits encourages the hope that the Empire is now self-supporting in regard to its supply of these essential materials.

The exhibit of the Gas Traction Committee illustrated the employment of coal gas as a substitute for petrol and petroleum products in motor vehicles, and comprised containers for the gas, meters for measuring the quantity used, cut-off valves, and a standard London motor-omnibus with gas fuel under compression. A different interest attached to the exhibit of the Nottingham Chamber of Commerce, consisting of embroideries. In 1913, more than one and a half million pounds' worth of embroidery was imported from Germany. The industry has been established here for many years, but progress has been slow on account of the economic conditions. An exhibit of hosiery knitting-needles indicated the progress made during the war by one firm, which is now producing more "latch" needles than were made before the war by all the British makers together. About 90 per cent. of the world's needles were made in Germany before 1914, and the cutting off of supplies brought thousands of our hosiery and underwear machines to a standstill. The Bradford Technical College sent specimens to the Exhibition dealing with aspects of technical manufacture in which Germany excelled. Important results have been secured by combining the Continental and British system of worsted yarn manufacture. The cloths produced as a result of this method are said to be equal in all respects to those obtained by using the Continental system throughout.

If the aim of the British Science Guild in organising the Exhibition was to stimulate public

interest and confidence in the capacity of British science, combined with industrial enterprise, to secure and maintain a leading place among progressive nations, it must be admitted that the aim was fully achieved by the representative character of the exhibits displayed.

ARTHUR COHEN.

THE CLOVE INDUSTRY OF ZANZIBAR.

The clove industry of the Sultanate of Zanzibar (including the islands of Zanzibar and Pemba) is a unique example of a valuable economic plant, not indigenous to the country, having been introduced from abroad and developed until it not only became the most important agricultural endeavour of its adopted country, but enjoyed an expansion which gave it the premier place in the world's production of that article. It is stated on good authority, writes the United States Consul at Mombasa, that Zanzibar is the source of over 90 per cent. of the world's supply of cloves, the balance being furnished by the Molucca Islands of the Dutch East Indies and by Madagascar. The value of this product to the Arab planters of Zanzibar averages, roughly, £500,000 annually, the production varying widely from year to year.

Apparently no accurate census of the acreage and number of clove trees of the Sultanate has ever been taken, but using the known statistics of the Government plantations (about 6 per cent. of the total clove area) as a basis, the area actually devoted to the industry is approximately 54,000 acres, of which 36,000 acres are in the island of Pemba. This area contains some 3,700,000 full-bearing trees, planted about sixty-five to the acre, different plantations varying considerably in this respect. The average annual production of cloves per tree for the past ten years is about 5 lb., but every five or six years the production falls, for some unexplained reason, to less than ½ lb. per tree, while in other years it will run as high as 8 lb., or even more.

The trees begin to bud in January or February; picking commences in July or August, and lasts for four or five months. Actual deliveries to the market occur throughout the year, but are heaviest from November to and including February. The marketing abroad is usually done by European firms in Zanzibar, who have specialised in this trade for years.

The crop returns in recent seasons (ending June 30th) have been as follows:—

	Zanzibar. lb.	Pemba. lb.	Total. lb.
1912–13	1,085,630	3,652,880	4,738,510
1913–14	5,095,510	22,333,290	27,428,800
1914–15	6,822,200	11,598,615	18,420,815
1915–16*	4,576,005	21,691,810	26,267,815

* To March 21st.

The extreme variance from year to year may be noted from the above figures. 1911-12 was the largest production year in the history of the crop, notwithstanding that since then a number of young trees have come into bearing. There is apparently no reason for these differences other than the general statement as to the sensitiveness of the tree to even very slight climatic changes. The production of clove stems amounts to 18 or 20 per cent. of the clove crop.

Zanzibar's export of cloves from 1912 to 1915 were:—

To	1912.	1913.	1914.	1915.
	lb.	lb.	lb.	lb.
Europe	6,067,460	8,789,644	5,707,601	9,270,001
America	2,576,520	1,975,518	3,499,917	4,494,299
Asia	6,539,807	6,772,530	7,657,767	11,525,332
Africa	68,157	275,047	105,123	135,822
	15,251,944	17,812,739	16,970,408	25,425,454

India is the largest purchaser, taking nearly one half of the whole crop; the United Kingdom comes next, followed by the United States and France. The cloves are packed in bales of 4 frasilas (140 lb.) each. There is an export duty on this product of 25 per cent. *ad valorem*.

Many years passed after its introduction into Zanzibar before the Arab planters realised that in the clove they had found a valuable commercial plant, which was better adapted to the peculiar conditions of the climate and soil of the Sultanate than it was to its own native environment. Many tropical countries have attempted the cultivation of cloves, but few have experienced any material success. Even along the coastal plain of British East Africa, where climatic conditions are apparently similar to those of Zanzibar, every effort to establish the tree has met with failure. Rainfall, atmospheric conditions, natural drainage, and soil elements, have their bearing upon the successful culture of the clove tree, for it is only when all these factors combine at a certain ill-defined point that the plant will thrive.

Specialised labour also had its influence in maintaining the industry, for it is to be noted that generations of cultivators and pickers, who have known no other employment throughout their existence, have followed one another in the tasks of their forefathers. In no other way, perhaps, could the culture of cloves have been continued,

as the tree and its crop require expert management and handling. Even the financing of the plantations and crops has been carried on by the same firms and their successors for generations.

An all-important factor which has contributed to the success in the establishment of this industry in Zanzibar is the Arab and his ability to control native labour in a way which the European has never learned. Cheap labour, due to the practice of slavery (abolished in 1897), also had its influence. But even now, when the Arab no longer has the authority of the slave-master to enforce his wishes and must pay a monthly wage of about 14 rupees, his intimate knowledge of the native mind, and his patient tolerance of idiosyncrasies, render serious competition from the European a remote possibility. In this respect, also, it is hardly probable that a clove plantation, which requires many years to establish, and when in full bearing cannot be depended upon to produce a gross annual income of more than £9 or £10 per acre per year, would offer any real inducement to European capital and management. It is an industry peculiarly adapted to the temperament and ability of the Arab race. European participation in the business will probably continue to be confined merely to the marketing of the product, the cultivation and harvesting being left entirely in the hands of the Arab planter.

GENERAL NOTES.

British Prisoners of War Book Scheme.—Owing to the recent fighting on the Western Front, which has led to the capture by the Germans since March last of some 90,000 additional prisoners, the requests for books have of late enormously increased, and the authorities are greatly in need of more voluntary workers. The work appeals, more perhaps than that of most other war charities, to educated men and women. If, therefore, any Fellows of the Society can do anything to bring the scheme to the notice of those who may have some spare time which they would like to devote to interesting and useful war work, the Committee would be very grateful. They require regular whole-time or part-time workers to help in the various departments of selecting, censoring, sorting or packing books, and in filing, registration, correspondence, and other secretarial work. Sir Alfred T. Davies, K.B.E., C.B., Chairman and Hon. Director of the Scheme, Victoria and Albert Museum, South Kensington, S.W. (7), will be glad to forward information about the work to any inquirers.

Paper-making Materials.—The general scarcity of paper, in spite of the recent allocation of additional shipping for its importation, continues to invest the discovery of new sources of supply with great interest for manufacturers and traders. Though the present problem is largely one of shortage of ship's tonnage, the steady growth of the world's demands for paper renders it imperative that new paper-making materials should be brought into use if prices are to be kept down after the war. Among the materials examined at the Imperial Institute during the present summer have been grasses from South Africa, the Federated Malay States, Australia, and St. Helena. Samples of "Tambookie" and similar grasses from the Pretoria district gave a high yield of pulp of good quality, capable of conversion either into excellent brown paper or (after bleaching) into white paper. Lalang grass—which grows abundantly in the Malay Estates, and hitherto has been so little esteemed that on the rubber plantations it is regarded as a troublesome weed—was found on investigation to compare favourably as a paper-making material with Algerian esparto grass, though it is not quite so good as Spanish esparto. Bamboo grass from the Northern Territory of Australia came up to about the same standard.

Wasted Power at Niagara.—It is estimated that five million horse-power is being wasted by omitting to utilise fully the Niagara Falls. The annual value of the power going to waste is at least $50,000,000; and, meantime, important works are suffering from lack of power to operate at the full capacity for which they were designed. It is stated that industrial men on both sides of the Falls are anxious for more complete utilisation, and that the only obstacle is Governmental inertia. The proposed consolidation of the Niagara Falls Power Company, the Hydraulic Power Company, and the Cliff Electrical Distributing Company would be followed by expenditure of $15,000,000 on new equipment, and a total increase in output of 170,000 h.p.—*Electrical World* (New York).

Irrigation Canals for Chile.—A new irrigation canal in Chile, the Mauco, has been completed. It has a length of 72 kilometres, and will irrigate 4,900 hectares at a cost of $1,600,000. Two more canals, the Maule and the Lafa, are under construction. The former is to be finished in 1920, and the latter in 1919. Another canal is to be constructed in Melado, of 23 kilometres in length, to irrigate 31,118 hectares, at an approximate cost of $5,194,000. It is also intended to dam the River La Laguna, near Coquimbo, which will store 40 million cubic metres of water at a cost of $100,000; the lakes of Planchón, which will keep 55 million cubic metres, at a cost of $350,000; to dam the lake of Mondaca, to store 70 million cubic metres of water, to irrigate 8,000 hectares, and other canals at a cost of $1,860,000. The Inspectors of Irrigation have under consideration the irrigation of the valley of Petorca with the water of the River Choapa, the damming of the rivers Aconcagua, Tinguiririca, Diguillán, Lake Invernada, and Maule, and the irrigation of the Nilatine valley.

JOURNAL

OF THE

ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.2.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

FRIDAY, SEPTEMBER 20, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

SPECIAL LECTURES.

THE FREEDOM OF THE SEA IN WAR.

By Sir Francis Taylor Piggott, M.A., LL.M.,
Chief Justice of Hong Kong, 1905-12.

Lecture II.—Delivered May 9th, 1918.

If war were always waged on land, if fighting were no more than a trial of physical strength between the young warriors of the quarrelling nations, the freedom of the sea would remain undisturbed, and traders be left in peace to pursue their lawful avocations. Does this pacifist dream represent the traders' wishes? Frankly, I very much doubt it. To judge by all the talk about the freedom of the sea at this time, you would think it was their heart's desire. I am sceptical, for there is nothing in history to warrant a belief in their altruism. The secret of the whole matter is this: War is good for trade. To provide all the things needed to carry on war is a "lawful avocation." Call it "commerce" if you like; it is those increments of commerce, engendered all the world over by even the smallest war, which the neutral trader seeks to protect. If any one doubts this harsh judgment let him read the documents in which the sordid story is written. You cannot begin to understand the most complex of man's activities, war, nor hope to settle the problems which arise out of it, if you omit to take into account human nature; and money lies at the root of human nature. All the theories that have ever been spun into what is called the "Law of Nations," all the books that have ever been written about it, seem to me to leave human nature out of consideration. War will not be won, nor the peace kept, by theories. There are two facts which govern war—the fighting fact, that men will fight all they know how, and with anything they can lay their hands on; the trading fact, that when war is afoot the merchants will trade with the fighting men for all *they* are worth, and *in* anything they can lay *their* hands on; and the shippers will carry cargoes for them anywhere, and at any risk, so long as high freights are paid.

Wise men have been busy for centuries devising means which shall abolish these evils, or at least restrain them within bounds. They have elaborated two codes of rules. The first is to regulate the fighting and keep the beast in man under control. This code is known as the Laws of War, which—till in this war the beast got the upper hand—seemed to have achieved some measure of success. The other is known rather vaguely as International Law. It had so little success even before this war, to judge by the endless disputes to which it gave rise, both in the Prize Courts and the Chanceries, that it is not surprising to hear the opinion freely expressed that it has broken down altogether. The reason of this disaster is the thesis of this lecture. The theorist began at the wrong end, applied pressure in the wrong direction. He took the trader under his wing, and invented maxims for his protection against the belligerent, oblivious of the fact that they would also protect the enemy. In the development of this thesis, I must open some forgotten chapters of English history, with which at this time it is necessary that Englishmen should be more familiar than they are. England is fighting for her life, to-day with the armies of civilisation on her side. She was fighting for her life then, with all the world against her. It is not much to ask that men should know something of the story of that past.

I first deal with the effect of war on the freedom of the sea. That freedom of peaceful navigation, fishing, and trading, cannot be better described—the sea being the common highway of the nations—than as corresponding to the freedom of the King's highway. But the sea is also, and the memory of man does not

run to the time when it was not, the common battle-area of the nations. One of the purposes of a fleet is to destroy the fleet of the enemy. Fighting at sea is inevitable, and so are brawls upon the highway. And just as those brawls disturb the lawful avocations of peaceable citizens, so sea fights, the brawls of nations, disturb the sea-traffic of those nations which are not concerned with the quarrel. The trade-routes are no longer safe; merchant-ships may find themselves in the midst of a battle; they must set their courses by little circles rather than by great in order to keep out of range of gun-fire; there is a general disturbance which seriously affects our friends the neutrals. Nor is it possible to localise the fighting, restricting it to any specific area of the ocean. The enemy's ships must be fought where they can be found. A war between Japan and Russia might lead to a battle in the North Sea, just as a war between European nations has led to battles in the Pacific and the South Atlantic. To this widespread inconvenience the nations which are not at war are subject, inevitably; and in this large measure, therefore, the freedom of the sea is curtailed by war.

But a deliberate attack on the high sea by a belligerent upon the commerce or navigation of the neutrals, unconnected with any specific battle, would give rise to just remonstrance and compensation; might, if apology were not given and accepted, or if the attacks were persisted in, most justifiably lead to war.

So much depends on the accurate appreciation of this fundamental fact that, going somewhat ahead of my argument, it must very clearly be understood that nothing, not even imminent defeat, would justify seizure of neutral vessels trading on the high sea between one neutral port and another, far removed from the normal area of the fighting, not even though the cargoes taken from them might serve to turn the scale in favour of victory. Yet even in such circumstances, which, to make the point clear, I illustrate by vessels trading during the present war between, say, Bolivia and Peru, the freedom of the sea has a limitation imposed upon it by war, in what is known as the "right of search." The right of a belligerent, by his lawfully commissioned cruisers, to search neutral ships upon the high sea for cargoes which he is entitled to seize, "whatever be the ships, whatever be the cargoes, whatever be the destinations," is incontestable. And the correlative duty of the neutral ship to submit to be searched is equally incontestable, and may not be resisted. By this specific limitation also, the freedom of the sea is modified by war.

But that is by no means the full extent of the limitations which war imposes on the neutrals. Access to the enemy's ports may be blocked by a belligerent fleet, and neutral ships caught running the blockade are seized as prize. Breach of blockade is committed by running in or running out; the breach begins when the ship sets sail upon her voyage with intent, though the port be 3,000 miles away; and the breach outwards continues till the ship has completed her voyage, though her home port also be 3,000 miles away. So, neutral ships carrying contraband of war to the enemy may be stopped at any point of their voyage, taken to the nearest port of the belligerent, their cargoes overhauled, the contraband confiscated as prize of war, and the ship, except in certain circumstances, only then allowed to proceed on her voyage.

It is commonly said that international law sanctions blockade and seizure of contraband. Does it not strike you that the more accurate description is that they are interferences with neutral trade with the enemy, which would otherwise help him win the war? In the old Prize Court decisions you will find abundant references to "prohibitions" by the belligerent to the neutrals, and the language of the criminal law is turned on to the neutral merchant who "infringes" them. Terms of "law" are out of place, and the sooner they are abandoned the clearer will the subject become. The "offence" consists in getting caught. The neutral merchant knows the risk ahead of him when he sets out on his voyage, and he deliberately runs it. If he can get through to port so much the better for his banker's balance; and so much the better for the enemy who gets the cargoes he is in need of. There is no "law" dealing with the question which has any analogy in any other known legal system. It is just "catch as catch can," and that is all there is in it.

This is the interference with the freedom of the sea of which neutral and enemy so bitterly complain. But is it not justified? The neutral merchant is *assisting* the enemy; and if there is any clear "right" resulting from war it must surely be this, to prevent persons who have no interest in the war from giving such assistance. It is a right which both belligerents equally possess, though it is quite true that both may not be able to exercise it with like effect; but that raises the question of supremacy at sea, and to abate this clear belligerent right of war is by so much to diminish the effect of that supremacy.

Just as enemy property is, and may be, seized the wide seas over, so also may cargoes which are going to the enemy in the circumstances known as running the blockade or carrying contraband. These two principles of seizure stand precisely on the same footing—property of the enemy, because it is the enemy's; cargoes going to the enemy, because they are, or will in due course become, his property.

But, you may well ask, why should this clear right of the belligerent be limited, as is so confidently asserted, to blockade and contraband? Assistance to the enemy may, as we know too well, take many other forms. Surely the remedy must be commensurate with the disease! The question which your intuition has propounded is the question round which all the trouble with the neutrals has turned since wars began to be fought upon the sea, and still turns.

The neutral merchant, for all his so-called "innocence," is an exceedingly ingenious person —all persons are where financial profit is concerned—and he has spent, and still spends, infinite pains in devising methods for evading the belligerent's interference with his trade, and inventing reasons why this right of war should not be extended to cover his new tricks. The right depends on a very elastic principle; he seeks to make it rigid, boldly contending that all trade with the enemy which does not fall within those two categories, breach of blockade and contraband, is legitimate. I need not say that the enemy backs him up; and between them they have elaborated all sorts of curious theories, which have very successfully clouded the issue. To these theories I must invite your very particular attention, because they are in certain quarters as rampant to-day as they were a century ago. You will find that, however ingeniously they are varied, always the same question lies at the bottom of them—protection of enemy property; always the same question ignored—the effect on the belligerent.

The foremost of these theories is that "neutral trade is free," which nobody has ever denied. But, they say, it follows from this that neutral trade with the enemy is free, excepting always trade in contraband, and trade with a blockaded port. The fallacy is that these two cases are assumed to be arbitrary exceptions to a pre-existing right of trade in which the neutrals are compelled by a belligerent's cruisers to acquiesce. Some have imagined a theory of compromise, which presupposes equal rights in the parties to it. But "trade" is two-sided. It takes two parties to make a contract of sale. "Neutral trade" means what it says, neutral trade with neutral. When the trade is with the enemy it becomes "neutral-enemy trade," very different in spirit and in fact. To assert that that trade is "free" is to assume either that trading with the enemy, so long as it is not in munitions of war, is of no benefit to him, or that, if it does benefit him, the belligerent must put up with it because of the neutral's profit. What is this benefit? It enables the enemy to sell his produce, creates for him credit, which is his principal munition of war; with credit he can buy contraband goods from his continental neighbours, which not even the greatest fleet can intercept; above all, it enables him to purchase everything he needs to keep his troops fit, and his people in good spirits. To trade with the enemy is therefore to assist the enemy just in regard to those matters in which he most needs assistance. The assertion that the belligerent may not prevent that assistance when it comes by way of the sea is no more than an attempt to deprive him of that force with which a maritime State is endowed by its position—"sea-power." Its object is to render supremacy at sea of no avail.

But all history is against the contention. By "history" I mean the record of how nations have fought in the past upon the sea. "The maritime nations," as Mahan well points out, "are the wealthy nations"; and when they fight it is inevitable that each should seek to destroy not only the other's man-power, but also his wealth-power, for wealth is the sinews of war. In the great war which began in 1793, France and England were like two infuriated dogs—I am quoting Mahan again—who had "locked jaws over commerce, as the decisive element in the conflict." Had they not done so, the war would never have ended. Supremacy at sea is the great factor in victory. Anything that tends to limit its exercise is a weapon in the hands of the enemy, and that is precisely what all these doctrines of the neutrals aim at.

Now there are on record two special forms of attack on this neutral-enemy trade to which England has resorted in her wars, which have greatly helped to bring her victory, and against which neutral and enemy have loudly protested.

In the old days trade with the overseas Colonies was a monopoly of the Mother Country. But when during war the neutrals were allowed to participate in it, their vessels were seized as the enemy's vessels were, because by throwing open his monopoly the enemy sought

shelter behind the neutral flag. And so with his coasting trade, also a time-old monopoly. He sought refuge from the attacks of the English cruisers by allowing the neutral to carry it on on his behalf. In both cases we swept aside the fiction and addressed ourselves to the reality. If the neutral vessels were chartered by the enemy they were identified with the enemy; if they were engaging in the trade on their own behalf, or as carriers, they were giving the enemy the most direct and effectual help short of actual military assistance in the war. What right had a neutral shipowner to do this with impunity? It could not be undertaken, so said Sir William Scott, "without the hazard of rendering himself liable to be considered as giving immediate aid and adherence" to the enemy. It was, of course, assistance in its crudest form, and as such, from the time of the Seven Years War, England declined to recognise it as anything more than another form of the risk which neutrals chose to run for the sake of profit. Hence it has come to be known as the "Rule of 1756."

This, then, must be clear to you—that England's action was *not* an interference with the freedom of the sea; it *was* an interference with the purpose to which the neutral endeavoured to put that freedom, a purpose for which it was never intended — assisting the enemy; and England resolutely refused to admit that he did it as of right. "His Majesty," said Sir Joseph Yorke long ago, in answer to the complainings of the Dutch, "could not otherwise get out of the war with safety." To call this an attack on "neutral trade" is to misrepresent its fundamental characteristics It was action in self-defence, and justified by every known principle which guides human action, and of which all systems of law approve.

But the theory of the complete "freedom of neutral trade" was poor in conception compared with the vigorous assertion that "free ships make free goods." Knowing whence it emanated, there is something sublimely impertinent in the assertion of a neutral shipowner that he has a "right" to carry enemy goods free, always excepting, of course, contraband of war. The neutrals made no bones about what they meant: that the neutral flag imparted, as a natural right, its inviolability to the enemy's goods; that the neutral ship was a sanctuary wherein those goods might escape capture. Why, I wonder! I have never come across a satisfactory explanation of the ethics of the maxim, though there is much vague talk about the benefit of commerce to the world, and the necessity of preserving it harmless in time of war. Its motives are the reverse of altruistic. Historically it was a maxim devised by the sea-carriers in their own interests, and was always advocated by the carrier nations, the Dutch, and the United States when, in the earliest days of its existence, it decided to develop a mercantile marine which should rival, if not outstrip, that of the old Mother Country.

I would have you realise this fact at once—I will abundantly make it good—that at the bottom of all the doctrines which profess to protect the so-called "rights" of the neutral merchant lies no morality, nothing but self-interest. Here, then, on the threshold of the subject is a maxim which rests on fine words only, and fine words cannot entitle it to rank as a principle of the Law of Nations. But I hear, as it were the still small voice of conscience, "Is it not past praying for, since we accepted it in the Declaration of Paris?" I have not forgotten, and before I have done I will tell you something of the lamentable history of that dangerous document. For the moment I can only give you the briefest insight into it. Here are the words: "The neutral flag covers enemy goods except contraband of war." One would have thought that when the plenipotentiaries of the great maritime Powers were settling, as they believed they were settling, a new great principle of international law—one would have thought that when those who represented England, Lord Clarendon and Lord Cowley, were selling England's birthright for a mess of pottage—they would have been careful, to say the least, to use words that should accurately convey their meaning. But even with regard to principles of belligerency which have never been disputed, this statement is untrue; it omitted to record two other exceptions, blockade and embargo, in which the neutral flag does *not* cover enemy goods.

But I will very freely admit that as a carrier *privilege* it might be granted to a carrier nation by treaty, even by a fighting nation, in return for some great and equivalent benefit. It is a fact that in several of the early treaties which England made with Continental nations she did concede the privilege, especially to the Dutch. De Witt spent many years trying to induce England to consent, as other nations had consented. The prosperity of Holland depended on the development of its carrying trade. It was his duty as a statesman to develop it by all means in his power; and he could best develop it by

securing for it those vast benefits which would thus accrue to the free carrier when other nations go to war. But he never supported his diplomacy by assertions that this was a "right" inherent in neutrality; he bought the privilege at the price England demanded for it—alliance. "It was," Pitt declared, "ceded as a matter of favour, not given up as a matter of right."

And so it will be found in all the cases when, at the Peace Conference, this precious maxim, and so many others of its kin, go into the melting-pot, when the dusty despatches are opened and the Public Record Office gives up its dead facts. It has only lately come to the light of remembrance that when Fox went to the Foreign Office in 1782, his first act was to propose to Catherine the acceptance of this principle by England in return for an alliance with Russia, of which we then stood in great need. Pitt, in after years, challenged him with abandoning the old English principle of belligerency. Fox replied: "When I offered it to Russia I meant to give nothing without getting a full equivalent. . . . I was tendering [it] as an inducement to a great and beneficial alliance." But of the maxim he said, "as an axiom, it is supported neither by the law of nations nor of common sense." Yet, in spite of this, there are those who contend that because we have agreed to it in some treaties therefore we have admitted it to be a principle of the Law of Nations. Why, they do not know this elementary fact, that even in the Continental treaties, in which it figures largely, it appears in two forms of very widely different meaning. In one, the most common, it is an agreement that if either of the contracting parties be at war with a third State the other may carry on its trade with that State unmolested; may even carry its cargoes. The other is quite different, and very rarely found, for, I think, obvious reasons: "If the two contracting parties are at war with each other (which God forbid) then the goods of each may be carried on neutral vessels without let or hindrance from the other." In the first form the right of free carriage of enemy goods is granted to one neutral only; in the second, free carriage by *all* neutrals is conceded to the potential enemy; and when people talk about it being a privilege granted to the neutral with which the enemy has no concern, at least we have a right to say to them, "Verify your references."

Time will not allow me to pursue this important point. I must press on to dwell, all fallacies apart, on the insidious danger of this maxim. From being at its inception a carrier maxim—bad enough, that neutral carriers had a right to protect enemy property—it gradually developed into a vendor and purchaser's maxim, protecting the enemy's purchases from the neutral vendor. So this came about: that goods sold to the enemy, where the property remained in the vendor, could not be seized because they were neutral property; and if the property had passed to the enemy and was conveyed in neutral ships, then also it could not be seized.

If this maxim is a principle of the true Law of Nations then all the principles of belligerency which England has relied on in her wars, on which her supremacy rests, go by the board. This is the foundation of the "freedom of the sea" for which the enemies of England, in conjunction with the neutrals, struggled. Can you be surprised that Pitt declared he would resist it "to the last shilling and the last drop of blood?" This was not mere war-rhetoric. It was Pitt's deliberate estimate of the value of this principle in helping the enemy to carry out his design. What that design was is written in M. de Vergennes's "*considérations*" why France should assist the revolted colonies of America:—"Providence had evidently chosen that very hour for humiliating England and revenging on her the wrongs she had inflicted"; it "would afford an opportunity to reduce England to the condition of a second-class Power."

Wrongs! wrongs! Always this cry of wrongs committed by England on the sea. Here is what an American historian, Fiske, says: "During the autumn of 1778 and 1779, Prussian, Swedish, Danish, and Dutch ships were continually overhauled by British cruisers, and robbed of cargoes which they were carrying to France." Was there ever so flagrant *petitio principii*? Those seizures could only be "robbery" if the maxim had anything of international morality in it. If it had none then they were no more than the exercise of a legitimate act of belligerency.

I have brought you now to the stormy period of the American War of Independence, when these questions were so vehemently discussed But I crave your patience one moment longer while I deal with that admitted curtailment of the freedom of the sea in right of war which I have already mentioned, the "right of search." This right is so broadly stated that it inevitably gives rise to protests which have all the appearance of being legitimate. But, suppose a vessel searched and contraband going to the enemy found on board, which the belligerent has a

right to seize. The search was then justified, for how else was he to seize? If the cruiser was mistaken, then the search was not justified, and compensation must be paid. But compensation may not be considered sufficient to atone for this "insult" to the neutral flag. It would seem then to be a case of the innocent suffering with the guilty. But now look at the other side of the question. The denial of the right of search carries with it the claim to give sanctuary; and, even in the case of contraband, which cannot be seized without search, it involves the interposition of the neutral flag between the belligerents. These are the two stools of logic, and in spite of the hardship, the propensity of the neutral merchant being what it is, the right of search, even in its largest statement, must be accepted as the inevitable consequence of war. But in practice it is obviously controlled by checks and balances, of which discretion is the chief. No belligerent has either the ships or the time necessary to send cruisers roaming over the sea on a speculative hunt for contraband. Quite apart from the fact that no belligerent wants to pay enormous sums in compensation, search is governed by what are called "sources of information," and the right is in fact only exercised when there is reasonable suspicion that the cargo on board is seizable.

This, then, was the point in dispute between England and the neutrals from 1756 to 1815. The neutrals declared that their flag was immune upon the sea; England declared that it was not immune when it was used to cover assistance to the enemy. If England was wrong, what she did was in fact an "insult" to the neutral flag. But this cry of "insult" was the merest *camouflage* for the claim of the neutral to a *right* to carry enemy property, other than contraband, free. Unless this right could be substantiated, all the declamation about "robbery on the high seas" was jargon.

You shall judge for yourselves. Here are the facts of a "little activity" in the Channel at the end of 1779, by which time France had openly espoused the cause of the American colonists. A fleet of Dutch vessels came sailing through the Downs under convoy of five warships. There happened—blessed word so expressive of the Navy's ubiquity—to be a British squadron of seventeen ships-of-the-line standing across their course. Search of the convoy was demanded, and refused; there followed an exchange of broadsides, and, honour being satisfied, the Dutch flag was hauled down. Some of the convoy got away to the French port; but some being seized, their cargoes were discovered to be ship's timber and naval stores for the enemy. "Discovered" is another blessed word of many meanings. In this case we knew all about the loading of these vessels in the Texel, and had made vigorous diplomatic protests. These facts are sometimes omitted in the narrative, which dwells only on the "robbery" and "outrage" and "insult to the flag."

I should tell you that the Dutch maintained that they had a right to send these cargoes under the Treaty of 1674. For those who care to follow out that point, I commend to their attention Sir James Marriott's judgment in the case of the "Vryheid." He interpreted the Treaty, and held that it was not its intention that the Dutch "should become the transports of the enemy's Government for carrying free its stores either by sea or land."

But the French dockyards were in the greatest need of masts, and timber, and stores, for repairing their ships and building new ones. Without ships England could never be "humbled." If, then, the neutrals had a right to send these cargoes free, the enemy had a right to receive them free. It is seriously contended that England was bound to stand by and let these "transports of the enemy" pass down the Channel. This is the "freedom of the sea" which was claimed in war! It is not the true freedom of the sea. There was no such duty imposed on England. It was in right of war that she seized those cargoes; nay more, it was her bounden duty to her own people to seize them; she acted in self-defence, a right on the exercise of which the safety of the State depends.

But the neutrals were far too ingenious to be satisfied with a simple issue. They proceeded to complicate it by asserting that ship's timber and naval stores were not contraband of war! The theory of international law has this very grave defect: it does not define the terms it uses. Dispute as to its application therefore becomes inevitable. "Contraband" means things useful in war, obviously a very elastic term. Yet the neutrals gravely asserted that timber for building warships, masts, iron, hemp, and other stores, were not contraband. Can you be surprised that England declared that she would not accept the contention, and acted accordingly? It is true that the neutrals had no sinister design against England. They professed friendship for her; but this friendship was not to deprive them of the profit resulting from free delivery of cargoes

sold to the enemy; and for this they nearly came to quarrelling. I will carry conviction to your minds by quoting extracts from two despatches, which will give you the key to the situation. Sir Thomas Wroughton, our Minister in Stockholm, wrote in February, 1780:—"I am constantly assured that we give too great an extent to the appellation of naval stores, which being the natural and sole production of this country, such an impediment to their exportation cannot fail of being a great detriment to its trade and revenues."

And from Copenhagen, our Minister, Mr Morton Eden, wrote about the same time, in regard to the victualling trade:—"It was a point the Danes could never give up, nor would: it was the only production of the country, and the loss of this branch of commerce must be highly detrimental."

Hostile critics would have you believe that we flouted the neutrals demand, and continued to confiscate their cargoes. England is not absolutely blind to her own interests. She does not willingly offend the neutrals, except when they give her cause, for the simple reason that she must protect her own trade with them. She recognised the injury which *confiscation* of cargoes of neutral produce must inevitably cause these countries; and where there were no aggravating circumstances, she substituted *pre-emption*; in other words, she bought the seized cargoes herself, and paid for them. This satisfied her claim as a belligerent to prevent the enemy getting them, and should have satisfied the neutrals. To reject this, and still persist that the cargoes must go forward to the enemy, carries me a long way in my argument, that assistance to the enemy is at the root of all the trouble.

I have set the facts before you simply, and I hope fairly, in order that you should appreciate on what flimsy foundation the assertion rests, constantly made at the time of her great wars, and, of course, renewed to-day, that England is and always has been the "Tyrant of the seas"; and specially because it is these acts which statesmen like Lord Clarendon described as "acts of barbarism" when they forced the Declaration of Paris on the nation; and because it is on the same foundations that the German "Freedom of the Sea" rests. Also because it is essential that you should know the real facts about the two Leagues of Neutrals which were formed against England in 1780 and 1800, known as the Armed Neutralities. It is surprising how little you will find in the history books about them; astonishing that a large percentage of what you do find is wrong, and gives you an entirely false impression. The critics of our sea-policy point to the results of these two Leagues in witness of its perversity. Mr. Fiske, the American historian already mentioned, declares that the first brought about "one of the greatest and most beneficent revolutions in the whole history of human warfare"; and, I grieve to say, an English politician, Sir William Molesworth, in a debate during the Russian War, declared that the Armed Neutralities had achieved their object! It is all stuff and nonsense.

I have written the story of these Leagues at length elsewhere, but it will bear repeating. It is a true story, because it is drawn from despatches written at the time. The clock warns me that time is on the wing; but I crave your patience still further while I tell it to you as succinctly as possible.

In 1776, owing to the surpassing folly of the British Government, the thirteen American Colonies revolted, and there burst upon us the storm which had long been brewing, the War of Independence. The infuriated Americans sent Commissioners to every European State to gather ways and means for carrying on the war, and to stir up hostility against their oppressor. We may talk of these things now as they really were with perfect frankness, for they are history. Their avowed object was not merely to obtain recognition as a State, but to compass the humiliation of England. In two countries they were eminently successful, France and Spain; France, still smarting under the effects of the Seven Years' War; Spain, with another very old score to wipe off, the loss of her supremacy at sea. Louis XVI. hesitated; it seemed to him inconsistent with his dignity to ally himself openly with colonists in revolt, though not so to show his sympathy with them in secret. For two years he tried to keep up a show of friendship with England while sending supplies across the Atlantic, receiving in exchange what the Americans had to sell, especially tobacco, some of which, it may please you to know, went to fill the pipes of British sailors. But in 1778, yielding to the arguments of M. de Vergennes, he declared war, and Spain followed suit. Thus the war spread to Europe. To the neutral timber merchants and ships' chandlers an immense business was opened up; and the phlegmatic Dutchmen looked forward to great profits as carriers. Then occurred incidents in

the Channel such as the one of which I have told you—Mr. Fiske's "sea-robberies" of cargoes going to France; and the Scandinavian Powers sought counsel of Catherine of Russia, that strange woman whose ambition it was to sway the destinies of Europe.

The position of England was full of danger, standing alone in the world with war in both continents on her hands; so full of danger that the only way through seemed to lie in an alliance with Russia. Sir James Harris, afterwards first Earl of Malmesbury, was entrusted with the negotiations. Louis, for reasons of his own, sought to appease the neutrals, and abandoned the old policy of seizing enemy goods on neutral ships; but Spain adhered to the practice in maintaining the siege of Gibraltar; and Paul Jones, for the colonists, did what he could with the "Bonhomme Richard," raiding the Firth of Forth and the Humber and seizing cargoes. Catherine was watching and waiting. At times she raised Sir James Harris's hopes that she would consent to the alliance; at times her waywardness filled him with despair. Suddenly, the ostensible reason being the seizure by Spain of a neutral ship going through the Straits of Gibraltar, she sprang upon our bewildered Ambassador a Declaration, directed to the belligerents, which the neutrals, long prepared for it, were invited to join. This was the prelude to the First Armed Neutrality of 1780.

Very naively she set out with the statement that "all hope that her subjects would have peaceably enjoyed the fruits of their industry, and the advantages belonging to a neutral nation, had been unfulfilled." In order to secure them she proclaimed her intention of insisting on four principles, asserting that they were based on the primitive Law of Nations, one of which was that "goods belonging to nations at war, except contraband, shall be free in all neutral ships." To maintain these principles and protect the honour of her flag, a considerable portion of her fleet had been put into commission, "to go wherever honour, interest, or necessity compelled." She promised herself that her wishes would be accomplished by the assent of the belligerents to her proposals, and pointed to the proofs of the "sentiments of justice, equity, and moderation with which she was animated," which she had given in her war against Turkey. This, I regret to say, was denied by an honest admiral of her fleet, who declared that Turkish property had been invariably seized on board neutral vessels.

The English answer published in the books is a most unsatisfactory document. Sir James Harris himself afterwards described it as "ambiguous and trimming." The *real* answer which he was instructed to present to the Empress, and did in fact present, gave no uncertain sound. Lord Stormont wrote, "We cannot and will not subscribe to such doctrine, I have repeatedly told you."

For some reason which I cannot pretend to understand, Lord Stormont's instructions are omitted from the well-known "Malmesbury Correspondence," and had passed out of mind until they were unearthed a few months ago in the Public Record Office. I lay stress upon this now because undoubtedly the publication of the mutilated despatch in a book which has passed for many years as accepted history, has influenced opinion against us in foreign countries, especially in the United States; perhaps also in our own. It is well, therefore, that this should be publicly stated; that never, in spite of armed coalitions arrayed against us, in spite of all the denunciations levelled against us during the Napoleonic Wars, never did England, between 1756 and 1815, waver one hair's breadth from the practice of seizing enemy goods on neutral ships, which she held to be warranted by the Law of Nations. Lord Stormont's despatch proves this as to 1780; Pitt's speech proves it as to 1800; and a despatch of Lord Castlereagh, also recently unearthed, proves it for 1815. *He declined to allow the question to be discussed* at the Peace Conference; and it was not discussed.

Catherine succeeded, however, in getting a formidable number of nations on her side. Denmark and Sweden adhered at once; the United Provinces in 1781; Prussia and the Emperor of the Romans in the same year; Portugal in 1782; and the Two Sicilies in 1783. Mutual treaties were concluded in which her precious principles were embodied. She was declared to have won the applause of all Europe. Applause was incense to her nostrils; but it is sometimes organised from the prompter's box, and those who applaud are known as the *claque*.

But in spite of the troubles, and this array of the neutral nations, England did stand firm. The neutral squadrons did nothing; I doubt if their batteries were really intended to be of any more effect than the painted muzzles on the gates of Peking. The first Armed Neutrality became, as in a moment of confidence Catherine had herself prophesied, an "Armed Nullity."

Peace was signed in 1783; the "United

Colonies" became the United States of America; the echoes of the war were lost in promises to forgive and forget; the profits of war-trading vanished; the subject of neutral rights ceased to interest, and Catherine's draft code of Maritime Law, intended to create the new "Freedom of the Sea," went to its appointed place, the pigeon-hole. Peace reigned in all the world—for ten years. Then began the long struggle which lasted from 1793 to 1815, and the old dispute broke out again—what was the measure of assistance which neutral merchants might give to the enemy? Only, strange to say, Catherine now allied herself with England, and was vehement in her denunciations of the "six hundred monsters" who had slain the Lord's Anointed.

But the ingenuity of the other neutrals was not yet exhausted. Remembering how roughly the Dutch convoy had been handled in 1779, they proposed to invest their flag with a new sanctity; and hoping thus to put an end to the "right of search," turned their attention to another variation of the same claim, the "right of convoy." By this they meant that the belligerent—England—was to accept the statement of the commander of the escort that there was no contraband on board his convoy, and the ships were to be allowed to pass on—to the French ports.

Now if there had been an agreement as to what was contraband of war, it is quite conceivable that the English captains would have been told to accept the word of a naval officer. The neutrals were quite honest according to their lights, and endeavoured to prevent what *they* called contraband from being loaded on their merchantmen. But the old question of ship's timber and naval stores was still open. The neutrals still sold them and sent them to France—*down Channel!*—and persisted in claiming their freedom from capture. Down Channel! Really, reading the correspondence of that time one can hardly be surprised at the old claim to the Narrow Seas. The struggle on the sea had reached a pitch of great intensity; the French dockyards were working at fever-pitch repairing and building ships. The neutrals contended that they had a *right* to send to the enemy the supplies for ship-building he so sorely wanted, within sight of the cliffs of Dover. Surely Providence was never so tempted!

I beg you most earnestly, in these days when the old strife has been renewed, to appreciate the true position. It is so simple. There was no "law" prohibiting the neutrals from selling and sending their naval stores to France; nor was there any "law" prohibiting England from seizing the cargoes. It was just a risk which the neutrals ran with their eyes open, the risk that their cargoes would be seized. They ran the same risk at the hands of the enemy, if they chose to send their ship's timber to England. To turn this risk into an unchallengeable "right" is the "Freedom of the Sea" which the neutrals claimed then, it is the "Freedom of the Sea" which Germany claims to-day. How can you expect, now that all theories have been subjected to the rough test of war, that England can possibly accept it! But the theorists are again abroad, the old fallacies are being aired once more.

Well, the convoys were as roughly handled in 1799 as they had been in 1779. Catherine was dead; but Paul, her son, had ambitions of his own, broke away from the alliance with England which his mother had made, listened to the complaints of the Scandinavian Powers, and launched a new Declaration, in which there were the same old appeals to the primitive rights of nations, and to the applause of all Europe. The same four principles were laid down, with the "right of convoy" added, and England's acquiescence in them demanded, and of course refused. This, in briefest outline, is the story of the Second Armed Neutrality.

But there had arisen in the world a new force which for many years was to dominate it, was to concentrate in itself all human ambition and become the incarnation of power; a man who, sweeping aside the unstable Government of the French Revolution, absorbing the weak States of Europe, aspired to lay low that presumptuous little island, England, and wrest from her the supremacy of the seas—the man who, at the time of these happenings, was First Consul of France, Bonaparte. By a curious irony he has become as great a hero in England as in France. Adulation has been poured out in great libations at his feet. I am not going to dispute his claim to unrivalled military genius; but I sometimes wonder whether his correspondence at this period has been sufficiently studied. It does not bear the impress of a great mind. Nothing was too mean, too paltry, if it served his ends. He truckled to Paul, whom he clearly despised; fooled him to the top of his bent. So curiously did his brain work that he conceived that he, a belligerent, might be admitted to the League of Neutrals, and was coldly rejected. They were willing to sell ship's timber to him: with that he

must be content. But the safety of the cargoes was of greater importance to him than to them, and insistence on "free ships, free goods" was imperative. I must emphasise this, because the theorists refuse to recognise that this maxim is more beneficial to the enemy even than to the neutral; and not the theorists only, but statesmen whose knowledge of these grave matters is sometimes surprisingly shallow.

But Bonaparte was too astute not to appreciate the weakness of the neutral argument; must have been conscious that, with the question of what was contraband still unsettled, the claim of immunity for the neutral flag was much in need of strengthening. Two new theories were therefore launched upon the world. The seeds had already been sown in the earlier controversies, and had received some cultivation from writers of books; but their gradual development by Bonaparte may be distinctly traced till they took definite shape in the preamble of the Berlin Decree, and their recognition laid down as a condition of peace. These theories were: first, that war on the sea must be waged according to the same principles as war on land; secondly, that private property at sea must be immune from capture during war. Though they were presented as two independent propositions, they really meant precisely the same thing; were no more than a very clever new way of putting that old crude doctrine of the neutrals about the rights of their "free ships," dressing it up in new garments which appealed to the philosophers of the time.

It certainly is a tribute to Bonaparte's cleverness, that though England would have nothing to say to them, though Pitt denounced them, though Castlereagh declined to discuss them at the peace, they lived and flourished forty years after, when humanitarianism, commercialism, pacificism had gotten hold of the minds of many politicians. They became the pet theories of the Manchester School, and of the Philosophical Radicals, and also of the remnant of a great political party, the Whigs. Alas! they are alive still, finding some support even in England. I would have you beware of them, for they form the basis of the German "Freedom of the Sea."

My allotted time is already far spent, and I must content myself with two brief remarks, which I hope will show you the fallacies involved in these doctrines.

First, the fallacies have been ruthlessly exposed by the great American historian of the sea, Admiral Mahan, so lately as in his study of the "War of 1812," published in 1906. He points out that private property *is* always free from capture, and that to take it either on sea or land is just common theft, which war does not allow. But when private property is set in motion across the sea it becomes "commerce," and is merged in the national property. If it be commodities, it is part of the national wealth of the enemy; if it be ships, they serve to carry that wealth to the markets of the world, to carry munitions of war and troops, and if they were immune from capture the enemy's fleet would be freed from the duty of protecting commerce from attack, and could devote themselves entirely to fighting. "These words," Mahan adds, referring to the Berlin Decree, "struck directly at measures of war resting upon long-standing usage, in which the strength of a maritime State such as Great Britain was vitally implicated."

But secondly: the sophistry of these theories got the better of men's intellects during the Russian War, and were swallowed wholesale when the Declaration of Paris, which accepted the neutral maxim, was forced upon a blindfolded nation; as to which one word only. At the outbreak of the war our alliance with France necessitated an assimilation of maritime practice. We accepted the maxim "free ships, free goods," as the nation was assured in Parliament, for the duration of the war only. Yet when the war was over, it was accepted permanently, in contempt of this assurance, at the Congress of Paris. No warning word was uttered; it was a bolt from a clear sky. No despatches were ever published, in which the rhyme or the reason of it might have been discovered. A few speeches from pedants of the Milk-and-water School are all we have from which to glean some excuse for this radical alteration in our methods of waging war at sea. But we now know the reason for all the secrecy and the silence. Lord Clarendon and Lord Cowley privately informed the French Government that they *dared* not make the change publicly "in the face of the people." For why? They knew full well that the people, as distinct from the politicians, would never have accepted it. I am sure that it will be sufficient for me to say this: that all the talk you now hear about these two theories is nothing but a revival of the old Bonaparte doctrines. As Englishmen you will decline to accept them, because they were the most insidious of the weapons which he devised for the undoing of England.

But if they are to be made the basis of the

League of Nations, which men now talk of as the panacea for all the troubles of war, it is, for that same cause, which I hold to be very sufficient, doomed to failure. Believe me, their acceptance is all that is needed to ensure the "Freedom of the Sea" which Germany is planning to achieve to-day, and will be the prelude to the successful accomplishment of her dream, the domination of the world.

I speak now in no spirit of vain-glorious boasting of my faith in my country. If "England" means anything to-day, as I believe she does, it is because she has created the true Freedom of the Sea, and in peace has opened wide her ports to the merchant commerce of the world; it is because she has declined to allow a spurious freedom to be substituted for it in time of war; it is because when she has gone forth to war she has known what war means, and has held to the only principle on which war can be successfully waged—to be strong enough, when the stress of war compels her, to put forth all her power upon the sea, to prevent neutral assistance in any form from reaching the enemy. To that end Pitt laid down his great principles of belligerency, which denied all the doctrines of the Armed Neutralities, all the sophistries with which Bonaparte endeavoured to support them.

And if "England" means anything to-day, as I know she does, not to herself alone, but to the Allies, it will be for them, when the time comes for declaring the true law of the sea, to bring to the discussion an open mind, to discard all pre-conceived notions and theories, to abandon those pernicious things, maxims, and go back to principles, and by the light of cold reason to review the facts of the story of sea-warfare, which is the history of England. They will then—I speak with unbounded confidence—they will then at last agree that England's position has been fairly and rightly won, has been loyally held, not in her own interests alone, but as a great trust, in the interests of the world at large, and that every act of her belligerency has been compelled by the safety of the State, and warranted by the stern justice of war.

Not the dreamiest of pacifists but admits that his pet League of Nations must, if a swift malignant stroke should come from the rebellious State before the slow-moving economic boycott could be got to work, resort to force. Force is to be the ultimate sanction of the League, as it is of all mandatory bodies. Force means war, and the ultimate battle must be fought upon the sea. Therefore the League must hold the command of the sea; and supremacy at sea can only be maintained by those principles which have enabled England to achieve and maintain it. England is asked to share that supremacy with the other nations of the League, to bring her heritage into "hotchpot." She must see to it that those principles are maintained. There must be no carrying of *this* enemy's goods free under the shelter of a friendly neutral flag. There must be no immunity for *this* enemy's property from capture at sea. All the imagined benefits of commercial brotherhood will be as Dead-Sea fruit if *this* enemy defeats the League. There is no middle course. The League must win the last great battle, or *this* enemy will win it. And in the principles of English maritime warfare lies the only way of safety for the free nations of the world.

FORESTRY IN CHINA.

Writing in the *Indian Forester*, Mr. F. Sherfesee adviser in forestry in China, gives an interesting account of what has been done and what is intended towards the establishment in China of a forest service under the Ministry of Agriculture and Commerce. He states that China has suffered, and must continue to suffer, owing to the wholesale deforestation which took place centuries ago, and that it was not until the establishment of the Republic that the importance of forestry was recognised. To Mr. Chow-Tzuchi, recently Minister of Agriculture and Commerce, must be given the credit for the inauguration of a nation forest service so recently as 1916. Among others, an English expert, trained at Kew, namely, Mr. William Purdom, serves as the chief of one of the six divisions into which the service has been organised. The general policy laid down is as follows: To lessen the present scarcity and high price of timber fuel and other forest products by the afforestation of public lands unfit for agriculture and practically waste. To regulate stream-flow by the planting of river sheds and catchment areas. To protect and manage on forest lines such public forest resources as still exist. To encourage private owners to plant by supplying advice and practical assistance. To conduct a vigorous pro-forestry propaganda throughout China, showing to all classes of people the need of forestry, what it means to the country, how it affects health and prosperity. To train young men to become foresters, and what are called inspecting forest nurserymen, whose duties will be chiefly the supervision of the initial work of forestry. It is also intended to instruct and interest school teachers in the principles and importance of forestry in order that they may impress upon the general student-body what it means to the country, and what the State is doing to foster it.

PRODUCTION OF MENTHOL IN JAPAN.

About 85 per cent. of the peppermint grown in Japan is raised in Hokkaido, which, together with Okayama and Hiroshima Prefectures, produces practically all of the Japanese crop. In Hokkaido it is cut only once a year, in September. In Okayama and Hiroshima it is cut three times—in July, September, and November.

The preliminary steps in the manufacture of menthol, writes the United States Vice-Consul at Yokohama, are carried out by the farmers themselves, with the aid of stills of a simple design. The peppermint plants are first dried in sheds, or under cover from the sun, for thirty days. Then they are placed in the stills, where they undergo a process of steaming. The resulting vapours are led off through pipes into cooling chambers, are condensed, and deposited as crude peppermint oil. This crude peppermint is shipped to Yokohama and Kobe, where factories are equipped to subject it to a process of fractional distillation to obtain the full content of menthol. The residue of oil is further refined to the standards of purity required in the trade, and is known as peppermint oil.

Before the war about half the menthol crystals exported from Japan were sent to Germany. Since the outbreak of the war the United States has become the largest purchaser of these crystals, followed in order by the United Kingdom, France, and British India.

The price has varied from 8*s.* to 10*s.* per lb. in recent years, remaining most of the time near the higher mark. Improvements in the process of manufacture have kept the price within reasonable limits, in spite of a considerable increase in the demand since the beginning of the war.

The figures for production in Japan are not complete, but are given in the official returns as follows:—

	lb.		lb.
1912 . .	202,124	1914 . .	320,564
1913 . .	260,120	1915 . .	502,181

ENGINEERING NOTES.

Queensland Lighthouses.—Before a meeting of the Liverpool Engineering Society, Mr. Ramsbotham, Director of Lighthouses for the Commonwealth, gave an interesting lecture recently on the above subject. He explained that the towers of the lights consist of four-legged steel structures, subdivided into four bars and braced in the usual way. The height of their platforms is 42 ft. 9 in. above the concrete foundations, the focal plane of the light being nearly 6 ft. higher. The foundations differ for each light. Those at Coquet Island and Clerke Island offered no special features, both being above high water and not subjected to any wave action. At Dhu Reef, where the actual site of the light is 18 in. below h.w.m.s.t., it was determined that at a depth of 9 ft. 6 in. the coral conglomerate, intermixed with sand, was sufficiently dense to stand a load of 2·375 tons per square foot. For the Piper Island light, which is established on a coral reef, it was ultimately decided to drive a nest of five ferro-concrete piles under each pier, excavating and putting a reinforced slab, 19 ft. square and 3 ft. thick, on the top. The necessity of driving the piles to a "sett" was recognised, but none of them could be so driven. In the author's opinion, nothing can be allowed for skin friction for piles driven in coral, and he decided to increase the bearing area to 963 sq. ft., reducing the intensity of stress to 0·725 tons per square foot. Acetylene dissolved in acetone at ten atmospheres pressure is used, and there are ten cylinders, each containing 117 cubic ft., all coupled together. They are changed once a year. The light is turned on and off by a sun-valve, which is so delicate that the light has been seen to come into operation during a rainstorm. A pilot flame is always burning. The lights are of 1,500 candle-power, with a visibility of thirteen miles. So far—*i.e.* since 1913—no trouble has been experienced with any of these unattended lights. The first cost compares favourably with that of a manned light, and the running cost is only £30 against £578.

Ferro-concrete Ships.—These have apparently come to stay. A 5,000-ton vessel of this class was launched a few months ago at San Francisco, and has since undergone an eighty-mile-an-hour gale, with waves thirty feet high, and has behaved herself admirably, with absolutely no vibration. As to other vessels, says the *Daily Telegraph*, reports from the various reinforced-concrete shipyards in England, Scotland, and Ireland, show that good progress is being made in the construction of 1,000-ton sea-going barges for the Admiralty Department of Merchant Shipbuilding. Vessels of this class are urgently required, and the programme of construction already authorised comprises barges and other vessels representing some 200,000 tons of shipping, and a capital outlay estimated at nearly £4,000,000, apart from the cost of land and shipyard plant. On the designs adopted, the saving of steel is fully 70,000 tons on what would have been required for steel ships of the same carrying capacity. It is believed that a still larger saving will be effected when practical data become available as to the minimum proportion of reinforcement that may be employed with safety.

Sea Water and Ferro-concrete.—A question of great interest in connection with this matter was discussed lately before the Faraday Society by Professor Creighton, of Swarthmore College, Pennsylvania. He outlined the process of the corrosion of iron by brine, and pointed out that, in addition, auto-electrolysis may occur owing to the electrical potential differences which exist in commercial forms of iron as the result of the presence of segregated impurities. These differences, which are augmented by chlorides of the alkali metals, bring about galvanic action, which causes the iron

to go into solution at certain points with formation of oxide. Reinforced concrete, therefore, which comes in contact with brine or sea water will begin to deteriorate. As both iron oxide and the hydrated oxide occupy a larger volume than the corresponding amount of iron, there will be developed an enormous expansive force, which is sufficient to crack the strongest concrete and force it away from the reinforcing rods. The more porous the concrete, the more rapidly will this disintegration set in. The durability of reinforced-concrete ships is therefore a matter of considerable doubt, unless the sea water is prevented from coming in contact with the reinforcements. Such prevention may be effected by coating the reinforcements with a protective paint, or by applying to the outer surface of the concrete some material that will render it waterproof. The concrete should undoubtedly be made from cement of fine pulverisation, low in alumina and high in silica, as free as possible from gypsum, absolutely free from lime, slow in setting, and quick in hardening.

Reinforced-concrete Sleepers.—There has been always a well-founded reason against these sleepers, owing to their want of resiliency, notwithstanding their durability. Iron sleepers have been used in India and elsewhere in consequence of the scarcity or unsuitability of timber, but they have been condemned in rock cuttings and in broken stone, as against gravel ballast, where resiliency is noted. There is an article in the *Railway Gazette* of July 19th dealing with the general subject of railway construction as applied to reinforced-concrete sleepers. The article gives two well illustrated examples—the Meyrick and the Yoke patents—of doubled sleepers each on a separate rail, connected by occasional iron tie bars, where the want of resiliency has been counteracted by the interposition of felt and timber packing, these standing several tests. Australia and some parts of North and South America seem, owing to their abundant timber supplies, to be in no need of reinforced-concrete sleepers.

Electric Shunting Locomotive.—The *Railway Gazette* is indebted to Mr. G. Hughes, chief mechanical engineer of the Lancashire and Yorkshire Railway, for particulars of the above, which has been designed and constructed at the company's works at Horwich. The locomotive is of the accumulator type with batteries divided into two parts, so that the two portions can be used in parallel, to give a voltage of 120, or when working in series 240 volts. The control system provides series parallel control on motors at 120 volts or 240 volts. There are ten notches on the controller for both voltages. The 120-volt supply is used for shunting purposes, giving a speed of about 4·5 m.p.h. The 240-volt supply is for running from place to place, the free running being 20 m.p.h. on the level. The tractive force exerted at the rim of the wheel up to 2·3 m.p.h. is 5,400 lb., and at the hourly rating 2,500 lb. at 4 m.p.h. The locomotive was designed to handle three loaded 20-ton coal waggons (90 tons) on an incline of 1 in 180. The engine can be operated by one man, and when the work is not continuous this man can perform other duties, it being left without any attention, but is ready at a moment's notice to perform shunting work. The capacity of the battery will admit of 3·2 hours continual shunting, or a 4 hours' continuous run "light" on the level at an average speed of 20 m.p.h. During the dinner hour a boosting charge will give back to the battery 40 per cent. of its total charge, raising the shunting capacity to 4½ hours. The locomotive is fitted with a vacuum brake and hand brake. The vacuum is produced by means of a small electrically-driven exhauster worked from either half of the battery.

A New System of Goods Transport.—Mr. F. Dutton, superintendent of South African Railways, has written a paper on the above subject, says the *Engineer.* He divides the matter into two parts, a motor tractor and train following, and, secondly, what he calls a loco-tractor. The latter forms a narrow-gauge railway (without a steam locomotive, the power being actuated by petrol through a pair of wheels), with the broad motor wheels behind the petrol motor. The wheels being lifted up, enable a narrow-gauge pair of flanged wheels to act in support of what the writer calls wheel-ways, which are on the outside of the rails. A trial trip has been made with rails of 16 lb. per yard, grades 1 in 20, curves 50 ft. radius; no ballast except that furnished by the wheel-ways; sleepers 1,760 per mile; speed 18 miles per hour; rubber tires on wheel-ways 1,330 lb. per ton, and on rails 344 lb. per ton; weight 5,655 lb. on the driving wheels, and 3,000 lb. on the rails. The estimate per mile was £320 for permanent way, £250 for earthwork, £50 for tracklaying, £150 for wheel-ways, total £770. The trial seems to have been a complete success. The report does not seem to give the gauge of the railway, but it is, without doubt, the South African type of 3 ft. 6 in.

The Maintenance of Electric Locomotives.—Trains of seventy-five ore-laden cars, each averaging at least sixty-eight tons, are not uncommon on the Butte, Anaconda and Pacific Railway, and there are now 262,400 volt direct current locomotives in use—those of the freight type weigh eighty-two tons each—as well as three tractor trucks of about half this weight. The electrical maintenance of all the locomotives and the tractor trucks is undertaken by two electricians and an assistant, who do all the rewinding of armatures and field coils, besides attending to the car heating and lighting equipment, a feat that would hardly be possible on a steam system with so few men. The passenger locomotives are inspected electrically and mechanically every thirty to forty days. In actual practice not more than one hour per unit is required from each electrician at the period of inspection.

Railway Material for Australia.—Experiments conducted by a special investigational committee, appointed by the Chief Railway Commissioner in New South Wales shortly after the outbreak of war, with a view to discovering a method of producing locally manufactured accessories necessary for the construction of railway rolling-stock, have met with almost entire success, says the *Melbourne Age.* The discoveries of the committee comprise a locomotive superheater equal to any that has hitherto been produced in any part of the world; steel railway axles superior to Krupp's; steel railway tires which have demonstrated by actual test satisfactory life; a new type of Australian boiler plate; the utilisation of a substitute for tin; and the invention of a method of building up worn tramway rails and crossings so as to make them again useful, not once, but several times.

The Erith-Riley Automatic Stokers.—For the latest extension of their electricity works, involving boilers with furnaces 15½ ft. wide as before, the Corporation of Hull have placed with Erith's Engineering Co. an order, their fourth, for these stokers. This order is for the high-duty pattern, with one-third greater capacity than the previous ones, and suited for a normal duty of three tons an hour. As a recent sample of the coal allocated to the Corporation contained thirty per cent. of incombustible ash, as compared with eight to ten per cent. in their pre-war coal, the continuous-cleaning feature of the stoker will be called upon to deal with nearly a ton of ash an hour. Erith-Riley stokers, with a normal duty of three tons an hour, are also being delivered to the Bow power-house of the Charing Cross Co. This information is extracted from the *Times Engineering Supplement.*

Coal in Queensland.— The Ipswich deposits, twenty-five miles from Brisbane, occupy 12,000 square miles, and the greater proportion of them are worked in this field, but the most important are the palæozoic coalfield in the Burram, fifteen miles north of Maryborough. The quantity of coal won from the State during 1915 was 1,024,273 tons, valued at £409,342. Further deposits are expected to be developed, according to the *Engineer.*

The Captured Gun "Bertha."—This gun was employed in firing lately on Amiens. The tube, 26 ft. 3 in. in length, is mounted on a chassis quite twice its own length. The 11-in. gun points its 26 ft. nose skywards from the centre, and the rear part is covered by an iron awning, under which is the conducting trolley for the shells, which are stored in a truck immediately behind. Coupled to this waggon are three more, the first containing cartridges, and the remaining two being reserved as living quarters for the gun team. A technical expert present said that the gun was only good for 200 rounds. Fourteen men, according to the *Times*, are necessary to control her fire, and fifty men in all for every purpose. The shell weighs 620 lb.

GENERAL NOTES.

Paper Supplies.—It appears from a statement made at the offices of the Paper Controller that an addition of 10 per cent. has now been made to the country's paper supplies by the use not only of waste paper, but of home-grown timber, straw, and reeds, in the making of pulp. It is hoped that in time improved methods of making paper from native materials may be devised. So far they have not proved the most economical form of production.

Germany's War "Substitutes."—A writer in the *Frankfurter Zeitung*, discussing the question of transition economy in Germany, says: "Of the pre-war imports, of which the value was 10 milliards of marks, 5 milliards were raw materials and 3 milliards foodstuffs and tobacco. Some of these we have done without during the four years of war, while for some substitutes have been found. Many sacrifices have been made. In the cotton trade, of 1,700 spinning and weaving factories, only 70 large ones are working; in the silk trade, of 45,000 looms, only 2,500 are at work; in the oil industry, only 15 out of 720 businesses are still active, while in the boot and shoe trade half the firms are closed. And after the war, when millions cease from war work, much raw material will be required. . . . Many war substitutes will continue to be used after the war." In a statement issued by the Imperial Department of Economics it is claimed that the post-war position will not be so serious as might appear, "because the substitutes for textile fabrics invented during the war will gain in importance every year." The latest of these devices is the production from tree-bark of a fibre for weaving. The waste obtained in the process is said to be well adapted to replace coconut fibre.

A German Scout Biplane.—A German Pfalz single-seater biplane is described in a report prepared by the Technical Department, Aircraft Production, Ministry of Munitions. The construction is light and the design clean, and care has been taken to keep the fuselage of very good stream-line shape. The machine was found to climb to 10,000 ft. in 17½ min., and to 15,000 ft. in 41 min. 20 sec., the respective rates of climb being 360 ft. and 110 ft. per minute. The speed at 10,000 ft. was 102½ miles an hour, and at 15,000 ft. 91½ miles. The machine is reported to be stable laterally, but unstable directionally and longitudinally. It answers well to all the controls, but tends to turn to the left in flight. It is not tiring to fly, and is normally easy to land. The most novel feature is the fuselage, which is simply a light wooden framework, without any bracing, covered with two skins of three-ply wood arranged specially in different directions. The undercarriage is constructed of stream-lined steel tube, and the shock-absorbers are of rubber, which is somewhat unusual in German aeroplanes at present. The wings and wing bracing are a copy of Nieuport practice. The engine is a 160 h.p. Mercédès.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.2.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

FRIDAY, SEPTEMBER 27, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

SPECIAL LECTURES.

THE GERMAN "FREEDOM OF THE SEA."

By John Leyland.

Lecture III.—Delivered May 16th, 1918.

In the series of lectures of which this is the third and last the question of the freedom of the seas has been, and is being, treated from three points of view, or, perhaps one may say, in three periods of history. The general subject has been brought before the Royal Society of Arts by Mr. Fiennes, and the relation of the belligerent to the neutral in former wars has been dealt with by Sir Francis Piggott. It falls to me to lead you into a consideration of the much-discussed, but imperfectly understood, claim of the Germans as expressed in these days by German statesmen, and embodied in the proposals for the peace they desire. I need hardly say how surprising it is to us to hear the claim for the freedom of the seas urged so frequently by those who abuse it most. We shall investigate this question, and regard it also to some extent with relation to the declaration of President Wilson in his great address to the United States Senate on January 22nd, 1917. The freedom of the seas, as you will readily agree, continued untrammelled and unrestricted in time of peace, so much so, indeed, that it was not questioned or discussed before the war. It would be a great mistake, however, to conclude that it necessarily exists *per se*, and that if Germany were victorious it would continue to exist in any waters which that Power might control—let me say, in the Baltic, for example, or the Eastern Mediterranean.

It must be admitted that the expression or phrase of the freedom of the seas, as used by the Germans and others, has in it something vague and indeterminate. It may sometimes have been used with reference to the possibility of economic war following the clash of arms. Many people find great difficulty in attaching any precise significance to it. It gives rise to misunderstandings and doubts, and—dare I say it?—has been used on some occasions with the object of darkening counsel. The German Government, in its reply to the Pope's Peace Note, made a claim for "the true freedom and community of the high seas." The Austrian Emperor also declared, of the high seas, that "they rightly belong to all the nations of the earth."

Count Hertling, speaking in the Main Committee of the Reichstag, on January 24th, said there was no disparity between the German point of view and that of President Wilson. We know, in fact, how wide and deep the disparity really is. He added that, for the freedom of shipping, it would be highly important that strongly fortified naval bases on international routes, such as England possesses at Gibraltar, Malta, Aden, Hong-Kong, the Falkland Islands, and other places should be removed or dismantled—a suggestion to which President Wilson, on general grounds, would by no means subscribe, since also the Panama Canal has been fortified by the United States Government. The Imperial Chancellor made a special reservation with regard to President Wilson's limiting clause, whereby the seas would be free, except as they might be closed "in whole or in part by international action for the enforcement of international covenants." President Wilson, in an address before Congress on February 11th, adverted with some sarcasm to the fact that Count Hertling looked askance at any limitation of the freedom of the seas by international action in the interest of common order.

I have sought in vain for any clear, dispassionate and reasonable definition in German authorities of the meaning of the phrase as

used by them. Have the statesmen, jurists and merchants, who say the freedom of the seas is menaced by England, any definite facts in their minds, or are they saying one thing and meaning another? The former Imperial Chancellor, Dr. von Bethmann-Hollweg, spoke merely in general terms on the subject in August, 1915, when he sent a message to the United Press of America in the name of his Imperial master. "Far across the frontiers of Germany this peace for which we are striving, will," he said, "guarantee to all nationalities the freedom of the oceans." A few days later, at the opening of the Reichstag, he declared the securing of the freedom of the seas to be a German object, and he embodied in his remarks a protest against British domination. "For our own and other people's protection, we must gain the freedom of the seas," he said, "not, as England did, to rule over them, but that they should serve equally all peoples." Consciously or unconsciously he spoke as Napoleon had spoken before him. The now famous resolution of the Reichstag, carried by a majority of ninety-eight on July 19th, 1917, declared for an economic peace with the freedom of the seas assured. "Die Freiheit der Meere muss sichergestellt werden," were the words, but they were not further explained.

But, if we look in vain for a precise definition of the freedom of the seas, as demanded by enemy statesmen and politicians, we can determine at least what their phrase does not imply. It does not, and it cannot, imply a condition of things existing at sea in any times other than those of war. It would be manifestly absurd to connote the German freedom of the seas with the situation which exists in peace, for I cannot discover that the term has ever been used—save recently by German shippers and publicists—except with reference to the operations of war. The sea is the free and beneficent highway of the nations, unless or until it is disturbed by the oncoming of hostilities. It is the secure environment in which the nations live. It is disturbed neither by outrage nor by piracy. It is made secure by survey and charting, by pilotage and the lighting of coasts and waterways, and by the provision of everything that can conduce to the avoidance of the casualties which are incident to the career of the seaman. It may be described, as by a figure, as the atmosphere which the nations breathe. They are unconscious of it until it is shaken by the concussion and filled with the choking dust of an explosion of the fury of the nations raging against one another. The freedom of the seas exists unquestioned, unchallenged, and unrestricted in time of peace. It never has existed, and never can or ought to exist, in time of war. As long as belligerency exists on land, it cannot be banished from the seas. It is, indeed, a strange thing that the aspiration for freedom in war extends only to the sea, for no one has yet been found to maintain that the peaceful merchant and farmer shall go about their concerns undeterred in the very zone of war on land.

We are, therefore, brought to the conclusion that, when the enemy makes a demand for the freedom of the seas, his real object is, if possible, with the help of the neutrals, to shorten the arm of our Sea Power—to lessen its reach and weaken its stroke in the operations of war. If confirmation of this view be required, we shall find it in the writings of certain German naval officers, and before I go any further I will cite certain passages of very remarkable character. Rear-Admiral Carl Hollweg is the author of a very dexterous little volume, published in Berlin last year for propaganda purposes, which is entitled "Unser Recht auf den U-Bootskrieg." This is what he says with reference to the freedom of the seas:—

"It is our honest conviction that to-day we are fighting with the neutrals at our side, for their future rights on the sea. And therein lies the great significance of the U-boat warfare in the present struggle, that it will destroy the obsolete, harmful theory of the 'invincibility of sea-power,' which has hung like a sword of Damocles over the heads of the weaker sea-powers; and that it will tear the whip of hunger out of the hand of English naval despotism for all eternity."

The second extract is equally vigorous in its form. It is from an article on the same subject, contributed to the semi-official monthly *Ueberall*, by Lieut.-Commander Bierbrauer zu Brennstein towards the end of last year. He concludes thus:—

"For Germany there is only one 'freedom of the seas,' which is the liberation of the seas from the tyranny of England. England's outrageous power must be broken for ever. To achieve this end a strong and mighty Germany is required, and then the seas will be free. To achieve this, a strong and powerful German navy is also required. We must have defended naval bases in our colonies and also on the Belgian coast, where no Englishman may land with hostile intent. Germany will then be the real protector of the neutrals, and of the freedom of the seas. It must and shall be so."

Herr Winand Engel put the matter quite plainly, not beating about the bush at

all, in the Pan-German organ, *Das Grössere Deutschland*:—

"German policy is forced to secure for itself by all conceivable means domination over the world sea. I deliberately use the expression 'domination over the world sea,' and not the expression 'freedom of the seas,' which is common to-day. The latter expression is either dishonest or stupid. The sea is free to us only if we dominate it. If we do not dominate it, it may one day be closed against us."

Now this is a perfectly clear and honest avowal of a definite purpose. Grand Admiral von Tirpitz explained how this was to be brought about to Mr. Gerard, former American Ambassador in Berlin, just before the latter left Germany. "Our submarine warfare is going to bring Great Britain to her knees, and when we have her where she is to pay the price, that price will be the British Navy. With it and our own navy we shall then come to the United States and get what we want." What then, one may ask, would become of the freedom of the seas?

The Royal Society of Arts would not wish me to tarry longer in the heated atmosphere of these angry disputations and demands, but, if we are to understand the objects which are covered in some influential enemy quarters by the claim for the freedom of the seas, it is essential that we should be made acquainted with the pleas and arguments which are advanced.

We realise, among other things, also that fresh movements are afoot in that obscure region of what is known as International Law, where the belligerent and neutral face one another. It is a department of the Law of Nations which, beyond all others, requires and must receive illumination for the ascertainment and determination of principles, because it is now seriously contended, not only by the enemy but by some neutrals also, that the neutrals possess rights which may transcend in efficacy those of the superior naval belligerent. The obvious consequence of the acceptance of such a contention would be to weaken and cripple the naval belligerent in his operations against his enemy. This aspect of the question was fully dealt with by Sir Francis Piggott in the second of these lectures, and will not detain me here.

Before we go further, it is important to observe that the German freedom of the seas, strange as this may seem, is not incompatible with the operations of submarines ruthlessly attacking enemy and neutral alike, nor with the laying of mines by the Germans in areas where they may and do endanger shipping, both belligerent and neutral, on the highways of commerce. At the Hague Conference of 1907, Great Britain advanced every possible argument to bring about a limitation of the practice of mining, and a restriction of the destructive effects of mines, by proposing that if mines got adrift their construction must be such that they would become innocuous. Germany led the opposition to the proposed limitation, and was supported by Austria-Hungary and other Powers. Sir Ernest Satow on behalf of the British delegation, declared that the emasculated Convention which was arrived at was very unsatisfactory, and was not a final solution of the question. It took no account of the rights of neutrals or the principles of humanity. It imposed no restriction upon the belligerent from placing mines wherever he chose—in his own waters for defence, in the enemy's waters for attack, or on the high seas, whereby neutral navigation would inevitably run great risks and be exposed to serious disaster. Sir Ernest Satow intimated to the Conference that an act of this kind must not be considered lawful merely because a Convention had not forbidden it. The German representative, Baron Marschall von Bieberstein, repudiated with some warmth the idea that his country was inferior to any other in the quality of humanity—a remark which arouses strange reflections at the present time.

How little the real freedom of the seas has been in the minds of the Germans who claim it, and how little they have regarded the rights of humanity, was seen in the early days of the war, when a mine-layer, in the guise of a peaceful neutral merchant ship, scattered mines indiscriminately in the open sea on the main trade-route from America to Liverpool round the north of Ireland, whereby peaceful merchant ships were blown up with great loss of life. It was because of these wanton and reckless acts that the Admiralty adopted special retaliatory measures, and proclaimed a war area on December 2nd, 1914. How utterly regardless of the rights of belligerents and neutrals Germany has since shown herself by her scattering of mines, is too well known to need any recital here.

We are now free to pass on to a consideration of the larger question of the freedom of the seas in time of war, which is quite a different matter from the abuse of that freedom by those who claim it most vociferously. Their claims, we may be assured, will be urged on other grounds when the Peace Conference assembles.

They have spared no effort to bring neutral opinion to their side by holding us up to execration as violators of the principles they profess to uphold. It is unquestionable that a great prejudice has been aroused against us in the minds of neutrals, which may be deepened also by the recollection of certain of our acts in former wars, and by our long traditional claim to what was vaguely known as the Sovereignty of the Seas. Among the acts which have been charged against us as tyrannical and violent in our treatment of neutrals, was our seizure of the Spanish treasure ships, in October 1804, when Spain was yet at peace with us, though at that very time Napoleon was driving her to take up arms in his quarrel, and the captured ships were engaged in carrying wealth to the Power which was about to range herself among our foes. There was our seizure of the Danish fleet in 1807, which was, indeed, a violation of neutrality, but was justified by the knowledge we had gained of the damnifying clauses of the Treaty of Tilsit, and the act was followed by restitution of the Danish fleet, while Denmark was saved from Napoleon, the Baltic was kept open for trade, Sweden was enabled to preserve her independence, and the Tsar was led, as a measure of prudence, to give peace and a constitution to Finland. There has, in fact, been a sufficient explanation of every act which has been regarded as a violation by us of the Law of Nations. In this present war, the restrictions which we have set upon neutral navigation have been in part in pursuance of undoubted belligerent rights, which forbid the neutral to carry or transmit supplies to the enemy, and in part have been due to considerations arising from the necessary protection of vessels from destruction by submarine attack.

Having now arrived at a general conception of the character and objects of the German claim to the freedom of the seas, we may say something about that relic of mediævalism — the old English claim to the sovereignty of the seas, not because it possesses any real modern significance, but because, in association with the claims of other nations to the possession of certain parts of the seas, it became the subject of a famous controversy, wherein the great Dutch legist, Grotius, arose as the exponent of the freedom of the seas from such assumptions of control as were applied practically in the restriction of navigation, trading and fishing, and especially because also the authority of Grotius, by a palpable misuse of history, has been used by modern Germans to express their condemnation of our imputed tyranny at sea. The freedom of the seas which the Germans seek would have been abhorrent to the mind of Grotius, and an intolerable heresy. To cite the juridical interpretation of the *mare liberum*, based upon conditions which have long since passed away, and to urge its application to the undermining of our sea-power, is to travesty the meaning of history. The free sea of Grotius had to do only with the prosecution of trade and navigation in the normal times of peace. He never argued against the law of contraband or the capture of private property; he maintained both. Our claim to a certain sovereignty of the neighbouring seas was based on our purpose, manifested in the Ordinances of Richard I., Edward I. and Edward III., of maintaining peace and justice "among the people of all nations whatsoever passing through the sea of England." A salute to our flag was exacted, but we were for centuries the persistent exponents of the doctrine of the free seas in all seasons of peace. We maintained it, and set out to "punish delinquents, and afford redress to the injured."

Those were ages in which there existed the idea of legal possession of the sea. Venice laid exclusive claim to the Adriatic, Genoa and France to parts of the Western Mediterranean, Denmark and Sweden to the Baltic, Spain to the Pacific and the Gulf of Mexico, and Portugal to the seas south of Morocco and to the Indian Ocean. Such ideas inevitably tended, as time went on, to attempts to restrict by legal means the free use of the seas. Henry VII., strongly opposing such restrictions, concluded with Philip, Archduke of Austria and Duke of Burgundy, in 1496, the famous treaty of the Intercursus Magnus, which gave to fishermen of all nations leave to fish where they would without need of licence or safe conduct. Elizabeth asserted for England with the utmost vigour the right to navigate the open seas against the exclusive policy of Denmark and Spain. Her reply to the Spanish Ambassador in 1580, her instructions to her own Ambassadors in 1602, and her declarations on other occasions, lacked nothing of definiteness or emphasis. She could not have been other than an exponent and advocate of the freedom of the seas in times when English seamen were breaking Spanish monopolies, and carrying their shipping into every sea. At its very birth our sea-power found an abiding inspiration, and fixed for ever the traditions of the Navy, in an age fragrant with the breath of free intercourse, of the free sea, and of political

independence, which are our glory, and the best gift we have given to the world.

Grotius set out mainly to demolish one by one the pretensions of the Portuguese to exclusive trading and navigation in the waters of the Indies, which the redoubtable van Heemskerk had struck at by warlike measures in seizing Portuguese shipping. His arguments did not prevent the attack and defence of commerce from being the essential feature in the three Dutch wars. The right of warlike capture was in full operation, and unquestioned. No legislators of those times ever thought of applying theories on sea dominion and fishing and trading rights to the conditions of war. Charles I. did, indeed, resent the claims of Grotius, and entered a protest through his Ambassador at the Hague. He caused Selden to make his famous reply, but saw clearly the point that he could not command the sea so much by the discourse as by "the louder language of a powerful navy, to be better understood when over-strained patience seeth no hope of preserving her rights by other means." Cromwell's Navigation Act established a restriction of free navigation, but, as Twiss remarks, "all these pretensions are now a matter of history." Professor Perels, the eminent German authority on International Law, who was formerly a professor at the Naval Academy at Kiel, and afterwards Counsellor of the German Admiralty, speaking of the seas in peace, lays down the indisputable principle that the use of the sea, with a political, industrial or scientific object, belongs to all nations and cannot be refused to any of them.

We must nevertheless recognise and understand the fact that in all the wars of the past two centuries we have been denounced as exercising harsh dominion on the waters, and that the neutrals have been marshalled against us on many occasions. It was during the Seven Years' War that we first began to be described as the "tyrants of the sea," though traces of the same imputation may be found earlier, as in the famous political testament of Richelieu. The victories of Hawke and Boscawen, the downfall of French rule in Canada, the breaking of French power in India, the immense increase of commerce which we reaped, and the policy by which we rigorously employed our belligerent rights against offending neutrals, made us the first of world Powers, though it caused us to be less loved than we were feared. Those nations which had sought to use the advantage of trade with our enemies, began thereafter to take counsel amongst themselves against our universal control of the sea. Pitt foresaw that the Northern Powers might unite in armed alliance to protect their trade, and in 1780 the first Armed Neutrality came into being. The object of this movement and of the Armed Neutrality of 1800, was to set a limit to the full exercise of our maritime power, and the contentions put forward were substantially those embodied in the modern German claim, stripped of its wild absurdities. Sir Francis Piggott has very ably analysed the genesis and character of the Armed Neutralities in the previous lecture, and therefore nothing shall be said about them here to-day.

It is, however, most important to understand the attitude of Napoleon in the period before the second Armed Neutrality was concluded, because of its close analogy to that of Germany at the present time, especially with relation to rebellion against our sea supremacy which lies at the root of the protest. Peace was ever on Bonaparte's lips, on grounds of reason and humanity, but, as M. Driault says, in his book "La Politique Extérieure du Premier Consul," there was in his expressions "plus de sensiblerie que de sincérité." From the very battlefield of Marengo, on June 16th, 1800, he declared to the Emperor and King that the equilibrium of Europe was not menaced by France, but "by the power of England, which had so seized upon the commerce of the world and the *empire des mers* that alone she could resist the united navies of the Russians, Danes, Swedes, French, Spanish and Dutch." This appeal was directed primarily to the isolation of England and the destruction of her sea-power.

The First Consul continually exerted himself to represent us as the tyrants of the sea. The official papers of the French navy at the time were adorned with a representation of the Republic grasping the helm of a vessel on which —in bold characters—were inscribed the words "Liberté des Mers." It was mainly by his advocacy and denunciation that he brought the United States into alliance against us by the Convention of September 30th, 1800. In his "allocution" to the deputies of the Hanseatic towns on March 17th, 1811, he declared, "Il faut reconquir à la fois le droit des nations, la liberté des mers, et la paix générale."

We are indebted to the Poet Laureate for a masterly translation of Fichte's famous account of Napoleon, with Freedom of the Seas on his lips and Overlordship of the Seas in his heart. It should be marked well in these days when

the Germans are making their loud demands. Napoleon, says Fichte, was endowed with the two elements of heroism—calm perspicuity of intellect and firmness of will, but these were irradiated with no inkling of the moral vocation of humanity, which seemed to him a blind lump, either stagnant or moving in disorder. He thought that rare spirits were born at long intervals, "the like of Charlemagne, and of none other but himself after Charlemagne," and thus, deeming himself a master-spirit, "the very godlike and holy, the first principle of motion in the world's history," he set great forces in action.

"And the most immediate, indispensable tool of his ordinance was at this moment the 'Freedom of the Seas,' as he said, but thereby intended the 'Overlordship of the Seas' in his own hands; and for this most important aim, determined by his world-law, all the happiness of Europe must be sacrificed, all its blood flow—since for that purpose only was it there; and this mighty world-plan, which indeed overstretched the scope of one life-time, should be carried on after him by his dynasty, so long as until, maybe in another thousand years, another inspired hero might spring up, a new incarnation of the type of himself and Charlemagne."

At this point I will introduce to you a well-known German—no other than the famous Schiller—at whose curious whim we may smile. The poet, at the opening of a new century—the nineteenth—addressed certain verses, which are ascribed by the critics to his third period, to a friend, mainly on the subject of freedom. He appears to have been infected with the glamour of the Napoleonic ideals, at a period before his country had been severely chastised at Jena and Auerstädt, and this is how he speaks of us Englishmen. You will allow me to render his verses in the form of prose.

His trading fleets sends the Briton out, greedy as the arms—he means the tentacles—of an octopus, and he will close the realm of the free Amphitrite as if it were his own house. To the never yet seen stars of the South Pole—I fear the explorations of Cook, Flinders, and others must have ruffled the poet—he carries his restless, unbounded course. He examines every island and every distant coast—only Paradise he does not reach! *

* "Seine Handelsflotten streckt der Britte
Gierig wie Polypenarme aus,
Und das Reich der freien Amphitrite
Will er schliessen, wie sein eignes Haus.

"Zu des Südpols nie erblickten Sternen
Dringt sein rastlos ungehemmter Lauf;
Alle Inseln spürt er, alle fernen
Küsten—nur das Paradies nicht auf."

—"Der Antritt des neuen Jahrhunderts."

Let us ask how our country has used that supremacy at sea which, throughout all the long centuries of our history, has been to us both sword and buckler? Have we used it to close or menace the pathways of the sea? Have we not rather used it on many occasions to hold it for the protection of the nations which have lain beyond it? The Germans, haunted by the shadow of their own militarism, have charged us with what they have called "Marinismus" or "Navalism." Once more, as in the long war with the French Republic and Empire, we are denounced as the tyrants of the sea, though the truth is palpable and beyond dispute that, with a deep instinct for freedom, and a wise political sense in our dealings with the nations, we have grasped the meaning of the sea for the benefit of the world. Its great traditions are in our blood; its potent influence is in all we have done; we have sought and discovered new pathways at sea; countless Englishmen have expended their lives and their treasure that the world might enjoy the advantages and riches, the profitable intercourse, and the free institutions which the safe sea can bestow. We have made the world as free to other nations as to ourselves. The British Navy has lain between many a country and the militarism that would have subjected it. The States of Central and South America owe their independence to our "Navalism," and the Monroe Doctrine itself was established and maintained because the British Navy made it effective by protecting the old possessions of Spain and Portugal from aggression.

Let Admiral Mahan speak of what the British Navy has achieved in maintaining the real freedom of the seas.

Why, he asked in one of his later articles, why do English innate political conceptions of popular representative government, of the balance of law and liberty, prevail in North America from the Arctic Circle to the Gulf of Mexico, from the Atlantic to the Pacific? And he answered that it was because the command of the sea, at the decisive era, belonged to Great Britain. In India and Egypt administrative efficiency took the place of a welter of tyranny, feudal struggle, and bloodshed, achieving thereby the comparative welfare of the once harried populations. What underlies this administrative efficiency? The British Navy, he answered again, assuring, in the first place, British control, and thereafter communication with the home country, whence comes the local power without which administration everywhere is futile. What, at the moment when the

Monroe Doctrine was proclaimed, insured beyond peradventure the immunity from foreign oppression of the Spanish-American colonies in their struggle for independence? It was, he said, the command of the sea by Great Britain.

The liberation of the seas for the free use of the nations has, in truth, been a progressive, consecutive purpose of our country. The Navigation Act, long maintained, had an economic purpose, and political economists in those times never wearied in pointing out the folly of restrictions of commerce. In 1826 the Act was repealed, more liberal rules were introduced, and in 1854 the coasting trade of England was thrown open to foreign vessels. The Germans forget that, under the much-contemned shield of the British Navy, the immense trade built up by the Hamburg-Amerika and Norddeutscher Lloyd lines, flourished exceedingly, altogether unfettered by any British action or exclusive policy whatever.

We turn now to the attitude of President Wilson and of American jurists to the question of freedom of the seas. When the President proclaimed the freedom of the seas to be of sovereign importance to his country, we well know that the freedom he had in mind had nothing in common with the so-called freedom which the Germans have demanded.

The conflict upon which he entered was directed, he said, to the suppression of a "warfare against commerce," which was, in effect, a "warfare against mankind" and "a war against all nations"—a war divested of all regard for the scruples of humanity, and of all "respect for the understandings supposed to underlie the intercourse of the world." He described German submarines as "in effect, outlaws," and as deserving to be dealt with as such. They had struck at the basis of "International Law," and had done so with a license—the words are not his, but those of Grotius—"of which even barbarous nations would have been ashamed."

The principle of International Law, said the President, had its origin in an attempt to set up some law which would be respected and observed upon the seas, where no nation had the right of dominion, where lay the free highways of the world. By painful stage after stage had that law been built up, with meagre results, indeed, after all has been accomplished, always with a clear view, at least, he declared, of what the heart and conscience of mankind demanded. This minimum the German Government had swept aside under the plea of retaliation and necessity, and because it had no weapons which it could use at sea except those of the submarine and mine.

President Wilson, at an earlier date, had imagined a condition arising from the war in which bitterness would not be implanted in the heart of any humiliated nation, in which the peace would be arrived at between equals, and in which a "freedom of the seas" would exist such, he said, as "in international conference after conference, representatives of the United States have urged with the eloquence of those who are the convinced disciples of liberty."

There can be no question that the President was referring, under the name of "freedom of the seas," to the immunity of private property at sea, save contraband of war. This matter is of very high significance, and its significance is likely to become more evident when the Peace Conference assembles at the close of the war. For Count Hertling claimed practical identity of view with the American President on the "freedom of the seas," except that he questioned the limitation proposed to be set up by the President, in that passage where the latter said the seas might be closed in whole or in part by international action for the enforcement of international covenants. The reference was doubtless to action possibly to be taken by the proposed League of Nations.

When the German claim is stripped of its absurdities, accompanied as it is by multiplied denunciations of ourselves, and is seen in its nakedness, it is revealed as nothing other than a demand for the immunity of private property at sea, or perhaps for the immunity of neutrals trading with belligerents—the immunity, for example, of any neutral willing in this present war to carry supplies to Germany. This may be the simple legal element of the claim. Count Bernstorff was reported, in September, 1915, to have indicated this as the actual meaning of the phrase—that "private property at sea should be immune from attack by naval forces." But the simple legal element which may be advanced at a Peace Conference is not enough. It must be regarded with suspicion, for, as Mr. Balfour has said, these missionaries of maritime freedom "are the very persons who preach and who practise upon land the extremist doctrine of military absolutism." They are the persons also who, by a strange contradiction of their own demands, make use of the submarine as a barbarous assailant of the freedom of the seas.

It must be admitted that the Americans have been very consistent in their attitude towards the question of the immunity of private property, save contraband, in maritime war. Benjamin Franklin procured a clause to be inserted in the Treaty between the United States and France in 1785, which granted this immunity. President Monroe took the same view in 1823, President Pierce in 1854, President McKinley in 1898, and President Roosevelt in 1903. This was the attitude, too, of the United States at the Paris Conference of 1856, and the same provision was embodied in the Treaty between the United States and Italy in 1871. At the Hague Conference of 1899 the following proposition was brought forward in a memorial presented by the representatives of the United States :—

"The private property of all citizens or subjects of the signatory Powers, with the exception of contraband of war, shall be exempt from capture or seizure on the high seas or elsewhere by the armed vessels or by the military forces of any of the said signatory Powers. But nothing herein contained shall extend exemption from seizure to vessels and their cargoes which may attempt to enter a port blockaded by the naval forces of any of the said Powers."

At the Conference of 1907, Mr. Choate made fresh proposals for the immunity of private property, and it is remarkable that amongst those who supported him were the German delegate, Baron Marschall von Bieberstein, and the Austro-Hungarian and Turkish delegates, all representatives of the present enemy Powers, while Great Britain, France, Russia, and Japan, Allies in the war, were all for the retention of the ancient right. Now that the great democracies of the West have grown so closely together, we may believe that the United States will not tarry longer in such uncongenial company as was ranged in this controversy with Mr. Choate. At least, it is certain that the League of Nations would never grant immunity at sea to the private property of a transgressor of its ruling.

It is right to observe, however, that the immunity of private property at sea has found many supporters in old and modern times. The Abbé de Mably and Azuni may be mentioned among the older writers. Brougham, not realising the great difference between sea and land warfare, was willing to conform the practices of the former to those of the latter. Palmerston seems to have toyed with the idea. Cobden was inclined in the same way, and John Stuart Mill, too, though the reasons with which the latter enforced his view read with strange unreality in the light of the present war. That is also true of all such proposals. Most of the German authorities are in favour of the immunity of private property at sea—Heffter, Bluntschli, Gessner, Von Holtzendorff, and others. Their attitude was inevitable in view of the situation of their country, which had all to gain by the proposals they favoured. Perels, however, gives an able summary of the reasons for maintaining the right of capture in these significant words: "War is a necessary evil; beyond question the confiscation of private property at sea is a necessary evil also; a nation whose principal military strength resides in its naval forces, cannot renounce this right without compromising its means of defence. The confiscation of the ships and goods of the enemy is, like the fighting on land, the object of maritime warfare. The latter has a character less cruel, without, however, weakening its effect, which is to compel the adversary to submit. By conceding complete freedom to the enemy's ships, he would obtain a great advantage, for these ships do not always confine themselves to inoffensive acts. Maritime commerce and commerce on land are two very different things; there are relations between the war fleets of a state and its merchant marine; merchant vessels may often serve the purposes of war, for which their crews are well fitted."

Although this eminent German authority was inclined to the views of Bluntschli, these arguments—which he gives dispassionately on the other side—seem unanswerable from the point of view of the supreme naval Power, and they are strengthened a hundredfold by the events of the present war. It has been argued that warfare against commerce at sea, which aims at impoverishing the civil population and arresting its industry, should be abolished. Why, it has been asked, should a soldier be forbidden to seize 1,000 bushels of wheat, unless he absolutely needs the supply and pays for it, while a naval officer may seize any merchant ship, and whatever may be in her — bullion, jewels, wheat or anything else—without the least suggestion that he has any real need of these things? What is the difference between 1,000 bushels of wheat in a ship and 1,000 bushels in a barn? The answer to this, and to other like questions, is that sea warfare differs entirely in its character and its laws from land warfare. How, in this war, have not the forecasts been falsified of some persons who have said that private property is

respected by the laws of land warfare, and not respected by the laws of war at sea ? An army can occupy a country, use its resources, make exactions from its people, and employ against its populations the extremities of military cruelty, under any kind of pretext, and in conformity with a "Kriegsbrauch" or other instrument. It can besiege cities, cut off their water-supplies, lay waste the surrounding tracts, reduce their inhabitants to famine, and bring them to misery and destruction. This invading army may be able to pursue the national army, and destroy it in battle or cause its surrender, or drive it over the land frontier of its country. A fleet cannot do any of these things. It can occupy nothing, and has no power of land action outside the range of its guns. It has no means of bringing the main forces of the enemy to action, if that enemy, as in the present war, chooses to remain in fortified ports. All it can do is to hold the communications of the enemy and maintain its own. If there were no capture of private property, naval operations would become immeasurably weaker as a means of endeavouring to force an enemy to submit. A fleet operates in an element that gives it a long reach, and enables it at times to exercise influence where it is never seen. There is nothing comparable in its action to the operations of an army.

That is why the British Empire can admit no so-called "freedom of the seas." The right of blockade and capture will be abandoned only with the abolition of war itself. The abolition of capture would mean in practice the prohibition of effective naval warfare altogether. "For two hundred years," wrote Admiral Mahan in his "Influence of Sea Power on History," "England has been the great commercial nation of the world. More than any other her wealth has been entrusted to the sea in war and in peace ; yet of all nations she has ever been most reluctant to concede the immunities of commerce and the rights of neutrals. Regarded not as a matter of right but of policy, history has justified the refusal, and if she maintain her Navy in full strength, the future will doubtless repeat the lesson of the past." We uphold the doctrines of blockade, capture and exhaustion, because their efficacy has been exemplified many times by the logic of facts, and is exemplified a hundredfold to-day. We naturally argue that a serviceable weapon cannot be abandoned until circumstances emerge over which we have no control that may render it obsolete.

I will conclude by quoting some pertinent observations which Mr. Balfour has made on the subject of the false freedom of the seas. He rightly warns us that, in the stress of war, or for the purpose of a hostile belligerent, so-called freedom of the seas, if accepted by the nations in any form, might in a single day be overthrown, and violence might find us unprepared.

"Could anybody," he asked, "suggest after our experience in this war, after reading German histories and German theories of politics, that Germany would be prevented from taking such a step by the mere fact that it was a breach of international treaties to which she was a party ? She would never hesitate—and the only result of the cession by the pacific Powers of their maritime rights would be that the military Powers would seize the weapon for their own purpose and turn it against those who had too hastily abandoned it. Thus we are forced to the sorrowful recognition of the weakness of International Law, so long as it is unsupported by international authority. While this state of things is permitted to endure, drastic changes in International Law may well do more harm than good ; for, if the new rules should involve serious limitations of belligerent powers, they would be broken as soon as it suited the interests of the aggressor ; and his victim would be helpless. Nothing could be more disastrous. It is bad that law should be defied. It is far worse that it should injure the well-disposed. Yet this is what would inevitably happen, since law unsupported by authority will hamper everybody but the criminal."

Mr. Balfour put this point in the clear light in which it must be regarded. We cannot throw away our shield and leave to the enemy his sword. We will not bow our heads to the stroke. We will make the seas really free to all men. We will not give them over to bondage under the name of a false freedom. It will, indeed, be an evil day for us if ever we are beguiled by empty phrases into listening to specious pleas for a deceptive freedom of the seas, whereby we may shorten the reach or weaken the stroke of that Navy upon which, in the noble words of the Naval Discipline Act, "our wealth, prosperity and peace depend."

Admiral Sir Edmond John Warre Slade, K.C.I.E., K.C.V.O., who presided at the last lecture, read the following statement :—

The interesting and important address which we have just listened to with so much pleasure

from Mr. Leyland, completes the course of three lectures on the "Freedom of the Sea"; and, with your permission, I will endeavour to review the subject as it has been presented to us by the three eminent men who have dealt with it.

In tracing the historical sequence of events, Mr. Fiennes has clearly demonstrated the important part the sea has held in the history of the world from the earliest times. He has shown that when man was first able to use the sea for purposes of transportation, there was perfect freedom for everybody. No law existed, and each man did as seemed best to himself within the measure of his own strength. Gradually combination came about, and as the arts of shipbuilding and navigation grew, we find sometimes companies, sometimes nations, banding together for protection and the furtherance of mutual trade. The sea was a highway and, like the highways on land at that time, people using it had to trust to their own right hand to maintain their right to travel along it in safety.

It very soon became evident that that body, whether an organised State or bands of freebooters, which controlled any portion of the sea exercised thereby a powerful influence on all persons or communities using that sea.

We thus find Greeks, Romans, Phœnicians, and Carthaginians fighting for the mastery of the Mediterranean, and the power that held it was for the moment supreme in the regions that depended on it for communications and trade. Similarly, in the north the Vikings exercised great influence both in this country and on the northern coasts of Europe.

Later, in the Middle Ages, England, France, Spain, Portugal, and the Netherlands fought each other for the same prize until, finally, at the beginning of the nineteenth century, were left only France and England. From the earliest days the object in every case was the same—to obtain the control of trade. In the earlier days the endeavour was to levy tolls on all trade wherever it could be struck at, and it was only in the later Middle Ages that this was seen to be uneconomical, and trade came to be protected on the high seas.

In wartime in all ages the control of the sea-lines of communication has had a profound effect on the war. The sea forms, and always has formed, the quickest route by which supplies, stores, and reinforcements can be carried from one point to another, so long as the countries engaged are in any way dependent on the sea. History tells us that in every war where maritime interests have been involved, the scales have been heavily weighted in favour of the side holding the control of the sea.

In the second lecture, Sir Francis Piggott has dealt with the subject from the point of view of the international lawyer.

Municipal Law has its origin in the endeavour of the community to protect the weak from the capricious action of the strong, and to introduce regularity into the conduct of daily life. International Law has the same idea as the basis of its inception, but with this difference that, while Municipal Law has the sanction of the State behind it, there is no sanction to support International Law, and this defect is fatal to its efficiency.

Endeavours have been made to correct this weakness by treaty agreement, and by tacit acceptance of precedent, each nation trusting to the honour of the others to abide by these understandings and to respect ancient customs. But the lesson of the war is the same as that taught by the history of all communities in the matter of Municipal Law and custom. There is a section of the community which will respect no custom nor any law unless force or self-interest drives it to do so.

The difficulties of arriving at any agreement on the principles of International Law have been far greater than those that have had to be surmounted in dealing with Municipal Law. There is no sanction that can be appealed to, and there are two distinct and antagonistic sets of interests to be reconciled, namely, those o the group of nations whose interests are continental and those whose interests are maritime. According as the Maritime Group or the Continental Group has been uppermost, so the ideas regarding the true principles of International Law have varied.

At the end of the great wars of the last century the Maritime School was in the ascendant. The long years of peace that followed 1815 were broken only by minor wars, in which the interests of the Maritime Powers were identical with those of the Continental Powers—namely, to facilitate by every means the trade with the belligerents. It thus came about that vital principles, the maintenance of which led us to the Battle of Copenhagen, were forgotten, and the protection of the neutral was considered more important than the maintenance of the rights of the belligerent. To this we owe the catch-words, "Free ships, free goods," which have always been the leading idea of the Continental School, and the negotia-

tions finally resulted in the signing of the Declaration of Paris.

The story of the negotiations leading to the Declaration of Paris shows very clearly how this has all come about. The Maritime Group, as represented by Great Britain, was faced with a dilemma. For reasons which we cannot consider here, she wished to enter into an offensive alliance, for the prosecution of the Crimean War, with the Continental Group as represented by France. The maritime interests in this war were not vital, and the real importance of them was forgotten except by a few. The politician of the day was obsessed by what I may call "The trade for all and anything for trade" doctrines, and could not see that the abandonment of principles, which we had found to be vital half a century before when we were fighting for our lives, would be equally vital when the trial came again. So he capitulated to the Continental School; but, as Sir Francis has pointed out, even then he was afraid of what he had done and, so far as he could, he carefully hid his actions from the knowledge of the country.

Apply this argument to the present war. We have the same two Powers in alliance, using the word in its broad and not in its technical sense, but the maritime interests now are as vital to the Continental as they are to the Maritime Power, with the result that the ideas of the latter have prevailed, and we have for the moment reverted to the position as it was in 1815. The antagonism between the two schools of thought remains, but vital necessities for the time have prevailed. When the world returns to its normal condition of peace, the conflict will revive once more, and we can only hope that our statesmen of the future will be more far-seeing and more courageous in defending our rights than those of the past.

Let us turn now to what we have heard to-day of the views of Germany. In this war she is whole-heartedly of what I have called the Continental School of thought, and she considers that there are no maritime rights at all if they interfere with her ideas of the proper prosecution of the war. All maritime rights that would assist her she upholds, while those that would not she condemns. Germany now condemns all the pretensions of the Maritime Powers as represented by the Allies; but, if she wins, she intends to enforce them, and more, so that the seas shall become nothing but a German lake. She understands the meaning of the pressure of sea-power from bitter experience, and she is determined to apply that pressure far more ruthlessly than we have ever done, if only she can get the upper hand. As pointed out by Mr. Leyland in the quotation he gave us, she is aiming at nothing short of the domination of the sea, and to understand what German domination would mean we have only to look at the countries that are now under her power.

Time does not permit my referring to Mr. Leyland's interesting arguments about the right of capture of what is called "Private Property" at sea, but that right lies at the root of all that is claimed for sea-power, and can no more be abandoned than we can give up our Fleet.

Now may I suggest to you, very shortly, a reason for the existence of these divergent views, and also for the necessity of maintaining our point of view against all adversaries?

There is no question of the freedom of the seas in peace. We must, therefore, conclude that the whole claim is directed to freedom of the seas in war.

The importance of lines of communication is apparent to all, and if any confirmation is required we have only to look at the works constructed by both sides during the war to keep the fighting line duly nourished. The sea is only a link in the lines of communication, but is a very important one, and if it can be interrupted it is a most serious blow at the efficiency of the side on which it is cut. Now the Central Empires are not self-supporting, and they are dependent on the sea, to a greater or less degree, for provisions and raw materials. For the Allies the sea is even more important than for the Central Empires. Geographically the lines of communication are the same for both sides, and, therefore, if they are controlled by one side the other side loses them. It is therefore necessary, in default of sufficient strength to keep the control, to attempt by agreement and treaty rights to redress the balance, but German treaties are one-sided—Germany may keep them, but the other party must adhere to them.

There is nothing analogous in land fighting except when a district or a town is surrounded and cut off from its base, but no sane individual, least of all a German, would argue that there should be conventions allowing free neutral trade with such a district, and yet this is what in effect is demanded in the German claim for the freedom of the seas. The issue may be surrounded with all kinds of sophisms such as there is no overlordship in the sea, etc., but the plain issue is this—the sea-line of communica-

tion is vital. It is the same for both sides. Therefore if one side is master of it the other loses it. Therefore the weaker side at sea must try to bluff the other out of the position of advantage by every possible means.

From this it becomes clear why there are two schools of thought—the Continental and Maritime. The former, the weaker at sea, wants to neutralise the natural advantages of the latter by agreement, if they are foolish enough to walk into the trap. And this is what is meant by the German freedom of the sea. The latter, unless they wish to court disaster, must maintain their full belligerent rights intact.

I have not mentioned contraband, as it is only a detail and does not affect the underlying principle.

Finally, let me say a word about the possibility of any real agreement on the subject of the freedom of the sea. It is clear that the acceptance and observance of a code of maritime international law is the first step to be taken, because without a code of law accepted and obeyed by all freedom becomes anarchy, and we revert to the conditions outlined by Mr. Fiennes at the beginning of his lecture. The difficulty is the absence of sanction, and when we have to deal with a nation that deliberately says "necessity knows no law," and deliberately sets herself to break every convention she has entered into with regard to the rules of war if she considers it to be to her advantage to do so, and then glories in the fact because she claims that she thereby increases her moral superiority over her enemies who have adhered to their engagements, it is hard to see any way out of the difficulty.

There is, however, this series of possibilities, which, I must confess, are somewhat Utopian.

1. To form a league of nations. A possibility, perhaps.

2. To codify the laws and customs of the sea. Almost an impossibility, seeing the conflicting interests involved.

3. Every nation that joins the league to agree that in case of breach of any of the laws agreed upon, she will join with her co-signatories in declaring war upon the offender if reparation is refused.

At present, so far as I can see, in this way and in no other can we hope to arrive at the freedom of the seas, but it will not be the German freedom of the sea. They will then be free within the limits of the agreed laws, and in case of war there will be only one set of interests to be considered, namely, that of the belligerents, because, *ex hypothesi*, there will be no neutrals. But when we arrive at this we shall be within measurable distance of the Millennium.

WOLFRAM ORE AND TUNGSTEN.*

Tungsten is a metal of very high specific gravity and high melting-point. It is used to some extent for filaments of metallic lamps, and in large quantities as an alloy with steel. It has, even in comparatively small proportions, certain hardening and magnetic effects, and in large proportions, *i.e.* from 12 per cent. to 22 per cent., it has a peculiar property of giving a material for cutting tools which retains its hardness at high temperatures. The use of this material allows the speed of machines and depth of cutting to be increased far beyond what was possible with older forms of tool steel. Tool steel of this class has become an absolute necessity of modern engineering. When tungsten is mentioned in this report it refers both to tungsten powder and ferro-tungsten. Tungsten metal powder and ferro-tungsten are the basis of the manufacture of: (1) high speed steel; (2) magnet steel; (3) other tool steel containing tungsten. The percentage of tungsten used varies: (*a*) in high speed steel, 12 per cent. to 22 per cent.; (*b*) in magnet steel, 3 per cent. to 6 per cent.; (*c*) in other tool steel, 1 per cent. to 10 per cent. The other uses in this country for tungsten are: (1) electric lamp filaments; (2) contacts for magnetos in place of platinum; (3) in the form of tungstate of soda for fireproofing fabrics; (4) other minor uses.

The amount of high speed and other tungsten steels now being manufactured in this country under war conditions is approximately 20,000 tons a year, which is being distributed as follows: in England, 8,000 tons; in Russia, 3,500 tons; in the United States of America, 2,500 tons; in Japan, 1,000 tons; in Canada, 1,000 tons; in France, 2,000 tons; in Italy, 1,000 tons; in Australia, New Zealand and South Africa, 700 tons; to other Allies and necessary Neutrals, 300 tons, calling for about 3,000 tons of metallic tungsten or its equivalent in ferro-tungsten.

In peace time the quantity of high speed steel made by this country may be approximately taken at 40 per cent. of the above amount. High speed steel is used for: (1) engineers' tools, such as turning tools, planing and slotting tools; (2) twist drills, reamers, taps and screwing dies; (3) metal milling cutters, cold iron saws, and shell making tools; (4) valves in motor and aeroplane engines and magnetos.

The raw material from which metallic tungsten and ferro-tungsten are made is wolfram ore, alternatively described as wolframite or wolfram concentrates, which is mined largely in the British Empire.

* Report of Departmental Committee on the Engineering Trades after the War. [Cd. 9073.]

[A table given here indicates the chief sources of supply of wolfram concentrates and the average quantities shipped from the various countries in 1910, 1911, and 1912. Out of 8,639 tons produced in 1912, approximately 3,800 tons were produced in the British Empire. The production from Burma is increasing rapidly.]

The world's figures for 1913 are not available in their complete form, but the figures of the British Empire since then up to 1915 are recorded at the Ministry of Munitions. The output from the British Empire for the year ending August 31st, 1916, was 4,600 tons. The Committee is informed that as the result of war conditions there has been an abnormal increase of the output of wolfram ore n the United States, where the amount for the six months, January 1st to June 30th, 1916, is reported at 3,750 tons. It requires practically 2¼ tons of wolfram concentrates to produce one ton of tungsten.

At the outbreak of the war no tungsten powder was being made in this country. At least three manufacturers were making ferro-tungsten on a small scale. The greater part of the wolfram ore produced appears to have passed through this country. The bulk of it found its way to Germany, where the manufacture of metallic tungsten powder was carried on chiefly in association with large chemical works from which the necessary supplies of hydrochloric acid and other chemicals could be obtained economically. The tungsten powder was then sold by Germany to this country, and was used by steel makers for the manufacture of high speed steel, of which considerable quantities were exported to the United States, France, Germany, etc. Tungsten powder is also made in the United States of America and ferro-tungsten in France. There appears to have been no reason in the past, apart from organised German competition, including price cutting, why tungsten metal should not have been produced in this country. The value of the ore produced annually in the British Empire is estimated at £1,250,000; the value of the tungsten refined from this ore is estimated at £2,000,000, and the value of the high speed and other steels made from this tungsten in the British Empire is estimated at £7,500,000, all at war prices. High speed steel makers were content, before the war, to rely upon German supplies which were of satisfactory quality, and the trade, in spite of its importance, had not hitherto received full attention from English manufacturers. On the declaration of war the want of tungsten became immediately apparent. The manufacturers' stocks held here were practically three months' normal supply. The Admiralty took steps to ensure that all wolfram ore produced under the British flag was sent direct to this country. Reduction works were started, and there are now some eight or nine works in this country producing the requirements of the trade. It would appear essential, from the point of view of national safety, that the Empire should not again run the risk of being without tungsten metal at a momentous crisis, or during normal times. The present British manufacturers of tungsten doubt their ability to continue in the trade after the war in competition with German manufacturers —though this is not the unanimous opinion of those now engaged in manufacturing. It is apparent that under the British flag there is likely to be sufficient supply of wolfram ore for British requirements.

In order to supply the high speed steel which is necessary for the security of the nation in times of war, and for its prosperity in times of peace, it is necessary to provide tungsten in sufficient quantities, or its equivalent in ferro-tungsten. To do this two conditions are essential: (1) sufficient ore supplies; (2) works in the country capable of reducing the ore. As to the first condition, it appears that so large a proportion of the world's wolfram ore is produced in the British Empire that the object would be secured if British works had a first claim to the ore produced in the Empire. As to the second condition, sufficient works have been created in this country in the stress of war to meet all likely requirements, and if these works are maintained and kept efficient it appears only necessary to prevent the trade from being crushed by organised attacks by their competitors abroad, either by underselling or "cornering" ore supplies.

[The Committee suggests that the Dominions and Dependencies should be communicated with at once, and their views ascertained as to the following proposal made to carry out effectually the conclusions to which the Committee has unanimously agreed, namely that all wolfram ore or other ores containing wolfram, pay a penalty in a form analogous to an export duty on leaving the Empire of £25 per ton.]

As regards tungsten (tungsten powder and ferro-tungsten), the Committee's conclusions are: (1) it is essential that tungsten should be manufactured within the Empire in such quantities that the normal demands should be easily met, and a sufficient supply for export manufactured, so that in case of an abnormal demand for defensive or other purposes, an adequate supply shall be available within the Empire; (2) that the works manufacturing tungsten which have come into existence, either at the request of the Government or otherwise during the war, shall receive subsidies or special consideration as regards Excess Profits Tax in relation to the amount of money they have sunk in the industry, either by way of wolfram ore dressing plant, tungsten producing works, research work, mines or concessions for the raising of wolfram ore, and generally with a view to meeting German competition after the war.

PRUNE CULTIVATION IN FRANCE.

The cultivation of the prune in France is said to have been started at Clairac, in the Department of Lot et Garonne, by monks of that region. The principal varieties now grown, writes the United States Consul at Bordeaux, are the prunes d'Ente, prunes d'Agen, and prunes robe de Sergent. Formerly the prunes du Roi and prunes Saint

Antoine were also cultivated, but these varieties have been largely discontinued because they are more difficult to cook.

For processing, the fruit should be quite ripe before gathering. This fruit, especially the prune d'Ente, is generally found in the best condition for use in September. It seems preferable to let it ripen and fall naturally, as it is then easier to preserve, richer in flavour and colour, and heavier in weight.

If the fruit remains too long on the tree it is shaken down, but to prevent injury straw is spread under the tree, or the ground is softened. The prunes must be picked up promptly, at least once a day under each tree. They are then spread out for a day or two in a dry place, and afterwards placed in ovens to complete the drying. Formerly bakers' ovens were used, but others specially suited to the purpose have now been made. Three periods in the ovens are necessary, the first two to remove all the water in the prune, and the third to cook it. During the first period the temperature must not exceed 45° to 50° C. (113° to 122° F.); during the second period, 65° to 70° C. (149° to 158° F.), and it is said to be very important that the temperature should not exceed the latter mark. After each of these periods the fruit must be exposed to fresh air, and it is necessary to avoid disturbing the fruit while it is warm. The third period, to cook the prune, must have a temperature of 80° to 90°, or even 100° C. (176° to 194°, or even 212° F.). This operation must be conducted carefully to avoid burning the fruit. The length of each period depends upon the condition of the prunes, but is generally about six hours.

The prunes are next separated into eight classes, or grades, depending on the size of the fruit. The class is determined by the number of prunes necessary to make a French pound of 500 grammes (1·1 lb.). Prunes of the superior first grade require but 30 to 35 to the French pound, while there are 40 to 45 of the ordinary first grade; second grade, 50 to 55; third grade, 60 to 65; fourth grade, 70 to 75; fifth grade, 80 to 85; sixth grade, 90 to 95; seventh grade, 100 to 110; and eighth grade, 120 to 125.

The prunes are usually packed in wooden cases of 14 kilogs 200 grammes (31·2 lb.), having a net weight of 12½ kilogs (27½ lb.). For South American trade, cases of 50 kilogs net (110 lb.) are sometimes used, but only for the lower grades of fruit. Decorated tins of half kilog (1·1 lb.) and glass jars are sometimes also used to cater for special demands, but at present special containers are too expensive for profitable use.

OBITUARY.

John Randall Mann, A.M.Inst.C.E.—Mr. John Randall Mann, who has just died in his ninety-first year, was elected a Fellow of the Royal Society of Arts in 1889. He was trained in the offices of the well-known builder, Thomas Cubitt, and when a young man was engaged upon the erection of the front of Buckingham Palace. In 1856 he was appointed surveyor of works on the Osborne estate, Isle of Wight, a position which he held for 35 years.

GENERAL NOTES.

Progress of Irrigation in India.—An interesting and comprehensive review of the progress of irrigation in British India for the year 1916–17 has been issued by the Public Works Department of the Government of India, and affords a very good idea of the past history, present position, and future prospects of irrigation in the Peninsula. The total area irrigated by all the productive public works amounted in the year to slightly more than seventeen million acres. Towards this total the Punjab canals contributed nearly eight million acres, Madras three and a half millions, the United Provinces two and a half millions, and Sind one and a half millions. The return on capital outlay was the highest in Madras, where, excepting two systems, the canals yielded 13·2 per cent. The next province was the Punjab, with a return of 12·99 per cent., while in the United Provinces and Sind percentages of 8·55 and 7·57 were obtained. The mean for the whole of India was 8·81 per cent. Protected works irrigated totalled 385,000 acres, and gave a return of 1·08 per cent., while minor works of all classes irrigated altogether were about eight million acres. Among the large works contemplated are the Sukkur Barrage and the Sind canal system, which is now being investigated by a special staff, the Ghaggar Canal, and the great Sarda scheme in the United Provinces, and also five schemes in the Punjab.—*Board of Trade Journal.*

Coal Outturn.—The annual report of the Acting Chief Inspector of Mines shows that while there were only 2,814 mines at work in Great Britain and Ireland in 1917, against 2,847 in the preceding year, the number of persons employed in and about the mines under the Coal Mines Act increased from 998,063 to 1,021,340. Of these 811,510 worked underground. In and about the mines under the Metalliferous Mines Act, 12,476 persons were employed underground in 1917, and 8,024 above ground, a total of 20,500, compared with 19,455 in the previous year. The number of mines at work decreased from 468 to 452. In and about the quarries 43,631 persons were employed in 1917, against 48,196 in 1916. The output of minerals during the year was 295,401,139½ tons, coal accounting for 248,499,240 tons of the total and iron ore for 14,845,734 tons.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

FRIDAY, OCTOBER 4, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

SCHEME FOR THE PROMOTION OF INDUSTRIAL ART.

In view of the keen commercial competition which will probably ensue between Great Britain and enemy countries at the close of the war, the Council of the Society last autumn considered what steps they should take in order to carry out the object of their charter, "the encouragement of Arts, Manufactures, and Commerce"; and they came to the conclusion that they could not do better than resume their efforts to promote the union of Industry and Art in this country, with the object of improving the artistic and workmanlike qualities of British manufactures, and maintaining for British trade its proper position in the markets of the world.

Accordingly they appointed an Industrial Art Committee, which included, in addition to persons nominated by the Royal Society of Arts, representatives of the Arts and Crafts Exhibition Society, the Design and Industries Association, and the London County Council Consultative Committees on Silversmithing and Allied Trades, Book Production, and Furnishing and Allied Trades.

This committee, after making very careful inquiries among manufacturers, distributors, educational authorities and others, drafted a scheme, of which a copy is appended below. It is believed that it constitutes the first serious attempt to co-ordinate the various movements towards the development and improvement of Industrial Art, and to prevent the overlapping of efforts.

Meantime a scheme for the establishment of a British Institute of Industrial Art was being promoted under the joint auspices of the Board of Trade and the Board of Education, "with the object of raising and maintaining the standard of design and workmanship of works of industrial art produced by British craftsmen and manufacturers, and of stimulating the demand for works of real excellence." The principal feature of this scheme is to be a permanent exhibition in London of modern British works, selected as reaching a high standard of artistic craftsmanship and manufacture.

The Industrial Art Committee have been in conference with the Authorities of the Board of Trade and the Board of Education, and as the two schemes are considered to be mutually complementary, it is intended that they shall work in close co-operation.

The Right Hon. H. A. L. Fisher, M.P., President of the Board of Education, has consented to preside at a meeting to be held at the Royal Society of Arts on Monday, October 28th, at 3 p.m., when the scheme will be submitted for consideration. Amongst those who have consented to speak are Lord Leverhulme, Sir Charles Allom, Sir Woodman Burbidge, Mr. Kenneth Lee, Sir William McCormick, Mr. Gordon Selfridge, and Sir Frank Warner.

As the accommodation is somewhat limited, admission will be by ticket only, and Fellows of the Society who desire to attend the meeting are requested to apply to the Secretary without delay.

THE SCHEME.

I. *Objects.*

1. To encourage and co-ordinate movements towards the development and improvement of Industrial Art, with a view to maintaining for the trade of the British Empire its position in the markets of the world; and especially to stimulate closer mutual understanding and confidence between producers, distributors, educational authorities, societies with similar aims, and individuals interested in these aims.

2. To co-operate with Government Departments and other bodies in promoting exhibitions, and in particular with the Government Scheme for a British Institute of Industrial Art.

[The Exhibitions contemplated would consist of exhibits selected for their artistic and

workmanlike qualities, with the intention of stimulating production, commerce, and public taste.]

3. To initiate and encourage research, experimental and other work germane to the objects above indicated; to award grants for conducting such work; and to co-operate, whenever possible, with Government and other institutions founded for such purposes.

[It is considered highly desirable that researches should be made into a large number of materials in order to ascertain exactly their qualities and the uses for which they are most suitable. The qualities of many kinds of timber, *e.g.*, have not yet been scientifically studied.

The Authorities of the Imperial College of Science and Technology and of the National Physical Laboratory have intimated their willingness to co-operate with the Executive Committee of the Scheme for the promotion of Industrial Art in matters connected with research. With their great staffs of scientific men of the highest distinction, and their admirably equipped laboratories, these institutions offer facilities for work of this kind which are probably unsurpassed in the world.

Another object in view is the award of travelling scholarships to designers, buyers, salesmen, and others, in order to provide them with opportunities of widening their experience and cultivating their taste.]

4. To encourage propaganda work, especially by means of the facilities for lectures and papers afforded by the Royal Society of Arts within the scope of its Royal Charter, "for the encouragement of Arts, Manufactures, and Commerce," and those afforded by other bodies.

5. To raise a central fund to carry out these and such similar objects as may afterwards be determined by an executive committee to be set up at the public meeting to be held in October. The Royal Society of Arts shall be constituted trustee of the central fund.

[Sums given for special purposes by firms, individuals, and societies may bear perpetual designations to associate them with the donors' names, as is the case with other donations and endowments of which the Royal Society of Arts is trustee.

It is suggested that a sub-committee should be set up for each industry which should meet regularly and make recommendations from time to time as to the steps which it is desirable to take in order to promote the interests of that industry. The report of each sub-committee would be submitted to the executive committee, and considered by it both in regard to its general recommendations and to its financial requirements.]

II. *Administration.*

6. The scheme shall be administered by the above-mentioned executive committee, which shall consist of: (1) persons representing contributors to the central fund; (2) members of the Industrial Art Committee of the Royal Society of Arts, and (3) others engaged in work covered by the scheme.

7. Pending the constitution of this executive committee, the Industrial Art Committee shall act for it.

CANTOR LECTURES.

The Cantor Lectures on "The Effect of the War on the Economic Condition of the United Kingdom," by Edgar Crammond, late Secretary of the Liverpool Stock Exchange, and on "High Temperature Processes and Products," by Charles R. Darling, A.R.C.Sc.I., F.I.C., have been reprinted from the *Journal*, and the pamphlets (price 1*s*. 6*d*. each) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C. (2)

A full list of the lectures which have been published separately, and are still on sale, can also be obtained on application.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

MILITARY EXPLOSIVES OF TO-DAY.

By J. Young, O.B.E., A.R.C.S., F.C.S.,
Chief Instructor in Science, Royal Military Academy, Woolwich.

Lecture I.—Delivered April 8th, 1918.

The subject of explosives is one of the most fascinating branches of chemistry, although studied by comparatively few. Everyone has a general idea of what an explosive is, and yet there is no subject on which the laity are more intensely ignorant, and most seem ready to believe any of the fairy tales of wonderful new explosives which appear at regular intervals.

For instance, early in the war we heard of a French explosive called Terpenite, which killed Germans by the hundred and left them frozen stiff without a mark on them. More recently we heard of an American explosive, of which a thimbleful would lift St. Paul's from its foundations. The chemist who understood explosives did not need even to investigate the stories; he knew that they were mere fiction.

The fact is there have been no epoch-making discoveries in explosives such as, say, the discovery of nitro-glycerine, for many years. None are likely to be made until someone discovers how to dissociate elements into their primitive constituents in a fraction of a second, in the same way as radium does in a million years

or so; and there is little prospect of this at present.

Nitro-glycerine, discovered in 1846, still remains the most powerful explosive in practical use. Many useful advances have been, and are being made, but new explosives are merely new mixtures of old materials, given fancy names. The nations at war use practically the same explosives, and no one can be said to be ahead of the others.

I propose first to deal briefly with the principles governing the subject, since it is by the application of these that any claims for a new explosive must be decided. They were first laid down by the great French chemist Berthelot, in his work "Explosives and their Power" (la Puissance des Substances Explosifs), a work which can still be consulted with advantage by those interested.

Definition.

An explosive is a substance in which a chemical action, once started, proceeds with considerable velocity, and with evolution of heat and gas. It must be self-supporting, and independent of outside agencies.

When the substance is enclosed, the pressure of the gases bursts the envelope, and the shock gives rise to an air wave. We say the substance has "exploded."

The total energy evolved is given out as heat, and may be measured in the bomb calorimeter. But in order to utilise the heat for doing useful work a gas is required. This, by its expansion, propels the shell or bullet, or disrupts the surrounding material.

The power of doing useful work is proportional to the volume of gas per unit weight of the explosive and its temperature. The temperature is not known with any degree of accuracy, but if we assume that the specific heats of the gases evolved by different explosives are the same it will be proportional to the quantity of heat evolved.

Coefficient of potential energy. — The quantity of heat, and volume of gas evolved, can be measured with considerable accuracy in the bomb calorimeter, and the product—

Volume of gas per gram (reduced to N.T.P.) $\times$ calories per gram

is called the coefficient of potential energy, and affords a useful and reliable means of comparing the powers of different explosives, especially those slow in action, such as smokeless powders. Substances like water, which are gaseous at the temperature of the explosion, are reckoned as gases.

The following table gives such a comparison of some of the most typical explosives in use:—

Name of Explosive.	Volume of Gas per gram in c.c. = V.	Calories per gram = Q.	Coefficient = Q × V ÷ 1000.	Coefficient G.P. = 1.	Calculated Temperature $=\frac{Q}{C}$. Assuming C = ·24 C = Specific Heat of Gases.
Gunpowder	280 c.c.	738	207	1	2,240° C.
Nitro-glycerine	741 ,,	1,652	1,224	6	6,880 ,,
Nitro-cellulose (13 per cent. Nitrogen)	923 ,,	931	859	4·3	3,876 ,,
Cordite, Mk. I. (N.G. = 57. N.C. = 38. Vaseline = 5)	871 ,,	1,242	1,082	5·2	5,175 ,,
Cordite M.D. (N.G. = 30. N.C. = 65. Vaseline = 5)	888 ,,	1,031	915	4·4	4,225 ,,
Ballistite (N.G. = 50. N.C. = 50. Stabiliser = ·5)	817 ,,	1,349	1,102	5·3	5,621 ,,
Picric Acid (Lyddite)	877 ,,	810	710	3·4	3,375 ,,

The coefficients correspond fairly well with the results obtained in practical use. The temperatures are certainly too high, as no allowance has been made for the increase in the specific heat of gases at high temperatures, but they are in the correct order. The actual specific heat of gases at such temperatures is not known, and any correction introduced would still leave the matter uncertain.

An experiment quoted by McNab, in which diamonds were found on carbon rods exposed to the flame of exploding cordite, shows that the temperature was certainly above 4000° C.

The table shows that nitro-glycerine is most powerful, and that in mixtures of it with nitro-cellulose the power is proportional to the amount of N.G., which is in accord with practice. Also that the power depends more on the amount of heat evolved than on the volume of gas. Explosives like nitro-cellulose,

which evolve a large volume of gas, are deficient in oxygen, and the gas is mostly CO. In those like nitro-glycerine, where part of the carbon is replaced by oxygen, the gas is CO_2, and the diminution in volume is more than compensated for by the extra heat evolved.

Solid products of combustion are unable to expand and do work, although they absorb their proportion of the heat. They are inactive, and merely produce smoke and fouling. Fifty-seven per cent. of the products of combustion of gunpowder are solids, which explains its weakness and defects.

The temperature of explosion is of great importance in the case of smokeless powders, as it is found that the erosion and consequent wear of a gun increases rapidly with an increase of temperature.

As examples of different kinds of explosives, I first heat some ammonium bichromate in a test tube. At a certain temperature it ignites, and the internal combustion which takes place continues without further application of heat. Large volumes of nitrogen gas and steam are given off, and a residue of chromium oxide, many times bulkier than the original substance, is left.

$$(NH_4)_2Cr_2O_7 = N_2 + 4H_2O + Cr_2O_3 + \text{heat}.$$

It is a true explosive, but a very bad one. It gives little gas (440 c.c. per gram), little heat, and a huge residue.

A little gunpowder, when ignited, flashes off, and besides gas gives a cloud of smoke, due to solid residue.

A piece of cordite burns slowly, gives only a trace of smoke, and leaves no residue.

Some loose guncotton flashes off rapidly, because of its porosity, but leaves no residue or smoke.

Products of combustion.—The products of combustion depend on the pressure under which the explosive burns, except in the case of gunpowder. Smokeless powders, and most modern high explosives, when burnt under atmospheric pressure, give off oxides of nitrogen which are highly poisonous. But under fairly high pressure, as in a gun, the nitrogen comes off as free gas and is harmless.

A simple experiment will show exactly what takes place in a gun when it is fired (Fig. 1).

A tall glass cylinder is filled with water, and a wide glass tube, a little longer than the cylinder, is immersed in it. The tube is fitted with a cork and stopcock, and another cork, smaller in diameter than the tube, so that it can slide easily inside it, is fitted with a piece of glass tube to act as holder for a piece of cordite (about ·5 c.c.). I drop the cork with its piece of cordite into the tube, so that it floats on the water, then ignite the cordite, and quickly insert the upper cork, with stopcock closed. The cordite is seen to burn steadily, giving off gas which drives the cork and water to the bottom of the tube, any excess of gas then escaping.

The tube represents the gun, the cork and water the shell. As the cordite burns the shell moves forward, enlarging the space and preventing any dangerous pressures. In the ideal gun the charge has just finished burning as the shell reaches the muzzle.

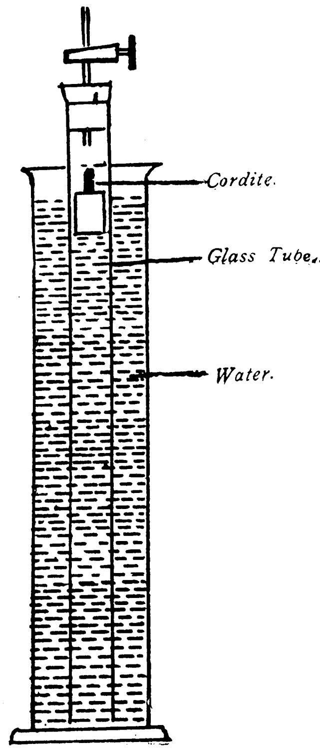

FIG 1.

In the actual gun the rate of combustion of the cordite increases as the pressure rises, but the charge is ignited over the whole of its surface simultaneously, and the total time of combustion is that necessary to burn through half the diameter, or thickness, of a single card or strip.

The gases contain 40 per cent. of CO and 13 per cent of hydrogen, and are inflammable. On opening the tap and applying a light, they are seen to burn. It is these which give the bright muzzle-flash of a gun, and also, some-

times, the back-flash when the breech is opened, which is a source of danger to the gunners.

On raising the tube and allowing air to enter, the gases turn brown, showing that under these conditions they contain nitric oxide (NO).

True explosion is of this kind, and is merely rapid combustion. The substance is ignited at the surface, and burns until the whole is consumed, the time of combustion of a charge varying with the size of the grains, sticks, etc. Detonation is a phenomenon of an entirely different order.

Detonation is the almost instantaneous disruption of a compound or mixture into its elements or simpler compounds, with evolution of heat and gas. Whereas the rate of explosion is measured in centimetres per second, the rate of detonation is from 3,000 to 10,000 metres per second.

Let us consider a 13·5 in. shell filled with lyddite of density 1·6: the velocity of detonation is 7,000 metres per second, the detonator is central, and the detonation has to travel through, roughly, one sixth of a metre. Hence, in $\frac{1}{6} \times \frac{1}{7000} = \frac{1}{42000}$th of a second the whole is converted into gas, occupying $1{\cdot}6 \times 877 = 1{,}242$ times the original volume at 0° C., but at a temperature of 3,375° C. The time occupied in the development of the gas is so short that the shell—or even the atmosphere alone—acts as tamping, and the substance detonates in its own volume, the theoretical pressure developed being 11,500 atmospheres, or 77 tons per square inch. For an instant the shell is intact and filled with gas at this pressure, the next instant it dissolves, and this giant force is applied as a blow to any body in contact with it. Guncotton will cut through its own thickness of iron, and it is probable that lyddite would destroy its own thickness of any material opposed to it, if detonated in intimate contact with it.

Such detonating substances are called *High Explosives*, and their immense shattering effect is due, not only to the volume of gas and quantity of heat, but also to the velocity of detonation and density of the explosive. Shattering power is proportional to

Volume of gas per gram × cals. per gram
× velocity of detonation × density.

The disruptive effect is exerted chiefly in the direction in which the wave of detonation is travelling. In a shell with a central axial detonator it is at right angles to the axis of the shell. This explains some of the apparently erratic effects of high explosive shells.

The effects of high explosive shells are very local, and to obtain full shattering effect it must be detonated in intimate contact with the body to be destroyed. To destroy armour-plate or concrete walls the shell should have a delay-action fuze, so as to allow it time to penetrate. Shells with instantaneous fuzes have been known to fail to damage a tank, because the shell detonated before touching it. On the other hand, we have had examples of German aeroplane bombs with such fuzes, which make no crater, as their main effect is lateral. These are meant for man-killing.

The very intensity of the effect of high-velocity detonating explosives diminishes the radius of their man-killing power, as the metal is blown to dust. A lower-velocity explosive gives larger pieces and projects them further.

Detonating compounds.—In the molecule of a detonating compound each atom is combined with others for which it has little affinity. Take, for example, nitro-glycerine ($C_3H_5(NO_3)_3$). The carbon atoms are combined with hydrogen, for which they have little affinity, and the nitrogen with oxygen and carbon. There is a constant tendency to decompose, and such a compound may be quite stable, while undisturbed, but the moment that the cohesion between the atoms is destroyed in any way it falls into its constituent atoms, which immediately reassemble and combine to form compounds of greatest stability, and give out energy in the process. We say it has *detonated*, and the detonation passes on from particle to particle through the mass.

$$2C_3H_5(NO_3)_3 = 6CO_2 + 5H_2O + 3N_2 + \text{heat}.$$

To start detonation.—Detonation may be started in several ways:—

(1) *By heat.*—For every compound there is a temperature limit at which it decomposes, and if a detonating compound be heated to this temperature it will detonate fully. But in most cases the heating must be very rapid, as most high explosives undergo a lower order of decomposition at a lower temperature, and do not even explode. Nitro-glycerine, rapidly heated, detonates with great violence, but heated a little more slowly decomposes with evolution of red fumes. Picric acid ignites and burns with a smoky flame, but if a little be projected on to a white hot plate it will flash off or even detonate. Similarly with T.N.T and others.

(2) *By shock.*—Any kind of percussive shock, such as a blow on an anvil, will detonate a

high explosive, if sufficiently intense; but a comparatively small shock will suffice *if of the right kind*. It seems as if for each substance a particular kind of vibration was necessary and this is the kind which it gives out itself when detonating. Examples:—

The shock of exploding gunpowder will not detonate guncotton, picric acid, T.N.T., or nitro-glycerine.

The shock of detonating nitro-glycerine will not detonate guncotton.

The shock of detonating guncotton will detonate nitro-glycerine.

Gunpowder is incapable of detonation. Fulminate of mercury will detonate all the above with the exception of T.N.T. cast into slabs, but with the addition of a little lead azide will detonate them fully.

Increasing the quantity of the initiator of detonation above a certain minimum has little effect. One gram of fulminate will detonate an unlimited amount of picric acid. No amount of gunpowder would do it.

A fulminate detonator provides combined shock and sudden heating, and is, therefore, very effective.

The explosive wave. — When a substance detonates, a wave which seems to contain a particular vibration peculiar to each substance is thrown out. This sweeps through the substance, detonating each molecule in turn. It is self-regenerating. This is Abel's theory, and is almost certainly true for pure chemical compounds. Berthelot's theory, that it is merely a wave of pressure which heats the particles which resist it, leaves many phenomena unexplained.

For instance: the more suitable the physical state of the substance for transmitting vibrations the greater the velocity of detonation, and the greater the certainty when once started. It is best when homogeneous and dense, up to a certain point. The velocity of detonation is approximately the same as that of sound in the substance, and sound we know to be a vibration. Gelatinised substances do not transmit vibrations well, and are difficult to detonate.

Liquid nitro-glycerine is easy to detonate, and the wave travels well. Frozen N.G. is crystalline. The separate crystals are more sensitive than the liquid, but they behave erratically, and a portion may be blown away undetonated.

Dry guncotton is porous, and the pores are filled with air. It is comparatively easy to detonate. Wet guncotton is quite incombustible, and difficult to detonate; but once started it detonates with greater velocity than dry, as water transmits vibrations more rapidly than air.

Detonation is more easily started in powder or crystals, probably because there is a less mass to take the initial shock; but the wave travels slowly, and may die out in a loose powder. Advantage is taken of this fact in detonating shells. Detonation is first set up in crystals or pellets, and transmitted to the dense filling.

Mixtures of high explosives which require different waves are always difficult to detonate. The wave which suits one does not suit the other, and may die out before it has gone very far.

The most striking example is cordite. It contains 57 per cent. of N.G. and 38 per cent. of guncotton, both sensitive substances which detonate easily. It is completely gelatinised. It can be detonated by percussion, but only the portion under the hammer; the wave dies out immediately. Even a fulminate detonator will only detonate about 2 lb., however large the charge, the amount being evidently proportional to the initial percussive blow. Two detonators will detonate, roughly, 4 lb.

Amatol, a mixture of T.N.T. and ammonium nitrate, is more difficult to detonate than pure T.N.T.

Another kind of detonation.—In the case of many high explosive mixtures much used at present, it is probable that the detonation is of a different order. The mixture contains at least one detonating constituent, the remainder being combustibles and supporters of combustion of the nature of gunpowder. Fulminate detonators are used. The detonator, besides delivering a shock, sends a wave of intensely heated gas at high velocity into the charge. The detonating constituent detonates, and this, along with the fulminate, sends a wave of hot gas through the mass, which causes the almost instantaneous combustion of the other constituents. For this kind of detonation porosity is an advantage, and also several detonators in a large charge. The charge should also be tamped. Mixtures for mining are always made in this porous form; when they set into a solid block, as sometimes happens, they are insensitive, and should be sent back to be reworked. Such detonation is more of the nature of a rapid explosion than true detonation, and is much slower. The average rate of mixtures in use is 3,000 to 4,000 metres per second.

Sympathetic detonation. — The detonating wave can be transmitted through air, earth, water, or other materials, and detonate charges at a distance, which are said to detonate in sympathy. As might be expected, the greater the facility which the intervening medium offers for the transmission of vibrations, the greater the distance at which charges will detonate in sympathy. This applies only to the true detonating wave.

Examples.—If dry guncotton primers are placed half an inch apart in air, and one detonates, all the others detonate. If they are separated by tin screens the result is the same. If placed in an iron tube, which would confine the wave, they may be five feet apart.

Berthelot states that when 100 gram cartridges of dynamite, 75 per cent. N.G., are placed on firm ground 30 cms. apart, the detonation of one will extend to all the others. If placed on an iron rail, the distance may be increased to 70 cms. He also states that five kilos detonated under water detonated other charges three metres distant, and the distance is proportional to the charge.

From this it is evident that in a shell dump the detonation of one shell would probably detonate all in contact with it, although others a few yards distant would escape. A torpedo may detonate the shells in the magazine of a warship, and a submarine mine may do the same. One submarine mine will detonate all others within a certain radius. Counter-mining depends on this principle.

Very rapid explosion may approach detonation in effects. To show this I ignite a small amount of gunpowder—about 1 c.c. It flashes off quietly. I put the same amount in a copper tube, left open at the upper end, and heat it with a Bunsen burner. By this means the whole reaches the temperature of ignition at the same moment, and when it explodes there is a report like that of a pistol.

A substance may either detonate or merely explode (burn), according to the treatment. For example—

Fulminate of mercury, when unenclosed and ignited, burns with a sudden flash. But when struck on an anvil, detonates with a sharp report.

A spot of nitro-glycerine on a piece of filter paper, when struck on the anvil, detonates violently. But a paper soaked in N.G. burns quietly with a greenish flame.

Picric acid, or T.N.T., as already stated, burns quietly when ignited, but can be detonated by percussion or the shock of a detonator.

Cordite can be detonated by hammering, although the wave does not travel far. When ignited it burns regularly.

But this only applies to small quantities. When large masses are ignited, they burn for a time, but the heat given out is almost certain to raise the temperature locally to the detonating point, and the remainder detonates. Cordite is a possible exception. The great explosions at Halifax and in North-East London are examples.

The qualities which are desirable in an explosive, intended for military use, may be summed up as follows:—

A.—*For use as a propellant in guns and rifles*

(1) It should generate a large volume of gas at a moderately high temperature; that is, be powerful, but not too erosive.

(2) The rate of combustion should be uniform, and adjustable by varying the size of the stick or grain; that is, it must be absolutely non-porous or colloidal.

(3) It must be uniform in quality, so that the shooting will not vary.

(4) It should have a high stability at ordinary atmospheric temperatures.

(5) It should not be liable to detonate by the shock of firing.

Cordite and N.C. powders comply fairly well with the requirements, and similar powders are universally used by civilised nations.

B.—*A high explosive for filling shells*

(1) Should give a large volume of gas at as high a temperature as possible. Incendiary effect is desirable.

(2) Have a high density, so as to get as great a weight as possible in a given volume.

(3) Have a high velocity of detonation, when destruction of material is the object.

(4) Be incapable of detonation by the shock of firing or impact against a target.

(5) Should detonate completely and with certainty when the fuse acts.

Picric acid, T.N.T., and amatol fulfil the requirements fairly well.

C.—*An explosive for military mines*

(1) Should give much gas and heat, with a moderate velocity of detonation, so as to have a great lifting effect.

(2) Should be safe under ordinary shocks, even the impact of a rifle bullet.

(3) Should give no poisonous gases when detonated. Craters may have to be occupied,

and mine galleries entered, shortly after the explosion.

(4) Should be detonated with certainty by a fulminate or similar detonator.

Ammonal, blastine, and several other explosive mixtures comply well with the requirements.

D.—*For hasty demolitions by the Royal Engineers.*

(1) It should be safe under the impact of a rifle bullet.

(2) Should have a high velocity of detonation.

(3) Should detonate completely with a fulminate detonator, and produce intense effects even when untamped.

Slabs of wet guncotton comply best, and have been used for a long time. Slabs of picric acid and T.N.T. are also used. Commercial explosives of all kinds are also used when the conditions are suitable, *i.e.* in back areas.

Materials for explosives.—Before commencing a description of the actual explosives themselves, a few remarks on some of the essential materials required for their manufacture may be of advantage.

Nitrates.—In the days when gunpowder was the only explosive saltpetre (potassium nitrate) was essential for the carrying on of a war. It was mostly imported from tropical countries, where it is most plentiful. During the Napoleonic wars the British command of the seas cut off the French from their overseas supplies, and threatened to stop the war in that way. But the French chemists studied the subject, and developed methods for the artificial production of saltpetre which are worked to this day, although neglected of late years.

At present nitrates, or their equivalent nitric acid, are just as essential as saltpetre was in the old days, as all explosives used in guns or shells are products of nitric acid. If the present war had started ten years earlier the Germans could not possibly have kept up their supply of nitrates. But the process for obtaining nitric acid from the atmosphere by the aid of electricity has now been well worked out. Huge works have been established in Germany, and there is little doubt that most of their supplies have been obtained from this source, and are practically unlimited. The process is being worked now in England.

Chlorates. — Potassium chlorate and ammonium perchlorate are much used. But the materials for the preparation of chlorates—electricity and common salt—are plentiful. Potash salts are almost a monopoly of Germany, but the small amounts necessary are easily obtained. There should be no danger of our running short of chlorates.

Cellulose ($C_6H_{10}O_5$).—This is essential for the manufacture of smokeless powders. Its purest natural form is cotton, and this is always used when available. Some chemists, who should have known better, thought that when the supplies of cotton were cut off the Germans would no longer be able to make nitro-cellulose. But it had been shown long before the war that wood could be made to yield about 40 per cent. of good cellulose, and that from this a stable nitro-cellulose could be made, not quite so good as that from cotton. There is little doubt that at present most of the German nitro-cellulose is made from wood-pulp.

Glycerine ($C_3H_5(OH)_3$).—This is essential for the manufacture of nitro-glycerine, which is a constituent of all powders used for heavy guns. The only source is animal and vegetable fats and oils, and the bitter cry from Germany in the early days of the war about the shortage of food fats meant that they were using their limited supplies for the manufacture of glycerine. Every cordite cartridge requires its own weight of fat for the glycerine alone. This statement will explain many things with regard to butter, margarine, coconut oil, copra, and similar tropical imported products.

Acetone ($(CH_3)_2CO$).—This is a fragrant liquid, boiling at 60° C., which has the property of dissolving both guncotton and nitro-glycerine, and is essential in the manufacture of cordite M.D. It is made by distilling calcium acetate, which is a product of the distillation of wood.

Aluminium, in the form of powder, is much used in explosive mixtures. It is permanent at ordinary atmospheric temperatures, but when oxidised gives out a large amount of heat. Its manufacture depends on having a suitable ore and plenty of electric power. Works have long been established in both Britain and Germany, and many places on the Continent.

Some electric furnace products, such as calcium-silicide, are also used, and various common metals and compounds.

The basic materials for the manufacture of high explosives for use in shells are all products of the distillation of coal, and come from the gasworks. They will be dealt with later. For these we are rather better off than other nations.

Explosive Mixtures.

Explosives may be divided into two main classes—explosive compounds and explosive mixtures.

Explosive compounds are substances of definite chemical composition, such as nitro-cellulose, nitro-glycerine, and fulminate of mercury, and are used in the pure form in only a few cases.

Explosive mixtures are mixtures of some combustible, which may or may not be an explosive in itself, with an oxygen supplier, the latter being usually a nitrate, chlorate, or perchlorate. Other oxidisers are available, and used in a few cases.

A third class might be added, consisting of mixtures of explosive compounds with addition of inert materials. Cordite and blasting gelatine belong to this class.

Nitrate mixtures.—Any one of the nitrates can be used as an oxygen supplier for an explosive mixture. *Potassium nitrate* (KNO_3) is best known and most used. It contains 40 per cent. of its weight of available oxygen, is not at all deliquescent, and mixtures containing it require no special protection from the atmosphere, except in tropical climates.

Sodium nitrate ($NaNO_3$) is a much cheaper salt, and contains 47 per cent. of available oxygen. But it is very deliquescent, and cartridges of explosives containing it must be made moisture-proof. In spite of this defect it is largely used in mining explosives of the cheaper variety.

Ammonium nitrate (NH_4NO_3) contains only 20 per cent. of available oxygen, and is very deliquescent, but otherwise possesses many good qualities. All of its products of explosion are gases, and are available for doing work, unlike the metallic nitrates. It is also an explosive in itself, and can be detonated into nitrogen, oxygen, and steam, with evolution of heat. In its natural form it contains water of crystallisation. This is driven off by heat, and the substance packed in barrels in the form of powder. If this is heated above 32° C. it changes its crystalline form and volume; the small amount of water which it still contains combines with the crystals and acts as a cement, so that the whole sets into a solid block. The same thing occurs with ammonium nitrate explosives, which should be kept below this temperature, as when they set solid they cannot be detonated.

Barium nitrate ($Ba(NO_3)_2$) contains 31 per cent. of available oxygen, and is used in some mixtures. This, and others which give colour to flames, are used in compositions for coloured flares.

Ammonium Nitrate Mixtures.

Ammonal.—One of the best known and most used of the ammonium nitrate mixtures is ammonal, in which use is made of the great heat given out by the oxidation of aluminium. A mixture of Al powder with the theoretical amount of ammonium nitrate for complete oxidation would contain 81·6 per cent. of NH_4NO_3. It would yield 1,578 calories per gram—nearly as much as nitro-glycerine—and 682 c.c. of gas. But such a mixture is difficult to detonate, and charcoal was added to make it more inflammable. One such ammonal made in Austria, and used by Austrians as a shell-filling, has the following composition:—

Ammonium nitrate . . .	81·0
Aluminium powder . .	15·0
Charcoal	4·0

The addition of di-nitro-toluene. or tri-nitro, makes detonation more certain, and the new ammonals contain one or the other. Military ammonal has the following composition:—

Ammonium Nitrate . .	65·0
Tri-nitro-toluene . . .	15·0
Aluminium (coarse powder)	16·0
,, (fine powder) .	1·0
Charcoal	3·0

It is a coarse black powder, very insensitive, and cannot be exploded by the shock of a bullet or application of flame. When heated strongly it inflames and burns. When thrown on a red-hot surface it flashes off. It requires fulminate detonators and strong tamping for best effect. With large charges, several detonators fired simultaneously are advisable. All cartridges must be hermetically sealed to preserve them from moisture, which quickly ruins ammonal. The velocity of detonation is about 4,000 metres per second, and the effect intermediate between that of gunpowder and dynamite. Power, three to four times that of gunpowder.

Enormous quantities of ammonal are now used in military operations. For charging grenades and bombs. For military land mines; some of our biggest and most successful mines were charged with ammonal. It is not now used as a shell filling.

In the charcoal ammonal a portion of the aluminium is fine powder to assist ignition, and the remainder coarse to resist oxidation on keeping.

Sabulite.—This is an explosive resembling ammonal, but calcium silicide, Ca_2Si, an

electric furnace product, takes the place of the aluminium. Its composition is as below:—

Ammonium Nitrate . .	78·0
Tri-nitro-toluene . . .	8·0
Calcium Silicide . . .	14·0

It is a granular, dark greenish-coloured powder. In properties it resembles ammonal, but is more sensitive. It is also used for mines, bombs, and grenades. It is detonated in the same way as ammonal, and has about the same power.

Bellite is one of the earliest ammonium nitrate explosives. It has the composition—

Ammonium Nitrate . .	83·0
Di-nitro-benzene . . .	17·0

It is used to some extent for mines, grenades, and bombs. It is detonated in the same way as ammonal and sabulite, but is less powerful.

Amatol.—This is a mixture of ammonium nitrate and T.N.T. in various proportions, which is now of great importance. T.N.T. does not contain enough oxygen for its complete combustion, and although the addition of ammonium nitrate increases the weight of the charge the increase of the heat given out more than compensates for this. The equation representing complete combustion of the T.N.T. is as follows:—

$$2C_2H_2(NO_2)_3CH_3 + 21NH_4NO_3 = 14CO_2 + 47H_2O + 24N_2$$

2×227 $\qquad$ 21×80

$2 \times 227 = 434$ grams of T.N.T. require $21 \times 80 =$ 1,680 grams of NH_4NO_3 for complete combustion. Such a mixture would contain 78·7 per cent. of NH_4NO_3 and 21·3 per cent. of T.N.T. It would give 1,042 calories and 892 c.c. of gas per gram, with a coefficient of 929, whereas pure T.N.T. gives a maximum of 732 calories and 987 c.c. of gas per gram, with a coefficient of 722. Various mixtures are now in use, the proportion of ammonium nitrate to T.N.T. being given as a fraction. Thus—90/10·80/20·50/50·40/60. Some of these are given fancy names.

The higher the proportion of ammonium nitrate the greater the difficulty of detonation, and the difficulty increases when the ammonal is melted and cast into solid blocks or slabs, as is necessary for shells. Hence the higher proportions are used in the form of powder for bombs, grenades, and mines, and detonated by fulminate detonators. The others, used for shell filling, are detonated by special methods, and will be referred to later.

All varieties of amatol are powerful H.E. The velocity of detonation is about 4,500 metres per second. All are spoiled by moisture, and must be waterproofed. All are practically smokeless. The products of detonation of the mining varieties are CO_2, H_2O, and N_2, and are non-poisonous.

The Germans also use ammonium nitrate explosives. Two used extensively for land mines and mined traps in evacuated territory are *Donarite* and *Westphalite*, both industrial explosives.

A typical Donarite has the composition—

Ammonium Nitrate . .	80·0
Tri-nitro-toluene . . .	12·0
Nitro-glycerine	4·0
Flour	4·0

There are several varieties of Westphalite. One has the composition—

Ammonium Nitrate . .	70·5
Di-nitro-toluene . . .	11·0
Flour	2·0
Sodium Chloride . . .	16·5

The NaCl is to diminish the temperature of explosion so as to make it suitable for coal mines.

These explosives are made into slabs which are wrapped in paraffined paper. Several are packed in a tin case hermetically sealed, and form a cartridge. Holes covered with waterproof paper are left in the tins for the insertion of detonators.

There are scores of similar explosives, and several varieties of each, used for industrial purposes, the weaker and slower varieties being purposely modified for special cases.

All ammonium nitrate explosives must be packed air-tight to prevent entrance of moisture, which quickly ruins them. When heated to a temperature of 32° C. the nitrate changes its crystalline form and increases in volume. This change, aided by the small amount of moisture which is always present, may cause the charge to set into a solid block which is almost impossible to detonate. Hence ammonium nitrate explosives should be kept as cool as possible, and never exposed to direct sun rays.

Other Nitrate Mixtures.

Gunpowder.—For centuries gunpowder was the only explosive, and it is still the best known. It has lost all of its importance as a propellant for use in guns and rifles, yet, owing to the many excellent properties which it possesses, it has at present a greater number of military uses than any other explosive.

Black gunpowder has the following composition:—

Saltpetre, KNO_3	75·0
Sulphur	10·0
Charcoal	15·0

When gunpowder was of the first importance, the charcoal was mostly made from willow, alder, and dogwood, as these were found to be best, but at present birch, poplar, and even common charcoal are found to be good enough for the purposes for which gunpowder is now used. The sulphur and saltpetre must be pure; the charcoal is the only variable constituent.

There is nothing new in the method of manufacture, and no details need be given. The various processes are to ensure (1) thorough incorporation of the ingredients, (2) fairly high and uniform density, (3) uniformity in the size of the grains, these being well polished to give them good keeping qualities. The incorporation used to last from four to eight hours, but has now been considerably shortened for the inferior qualities.

Gunpowder is used extensively as an auxiliary to the more powerful explosives. It is quite permanent when kept dry, but moisture completely spoils it. It has a high ignition point, 300° C., but then ignites readily, and burns quickly and with certainty. It is this certainty of action which recommends it for many purposes. It is comparatively weak, 57 per cent. of the products being solids, mostly K_2CO_3, K_2SO_4, and K_2S_2. These form a smoke cloud, but this is often an advantage for observation purposes.

The following are some of its present-day military uses:—

As igniting primer for smokeless powders.—Cordite and N.C.T. powders do not ignite readily, especially when in thick sticks, and a powerful flash is required. In separate ammunition, where the charge is in a fabric bag, a packet of gunpowder is fixed at one or both ends of the charge. In fixed ammunition for quick-firing guns, a percussion primer is screwed into the cartridge-case. This contains a percussion cap and one to two oz. of gunpowder. The flash from the powder ignites the explosive charge with certainty.

As bursting charge for shrapnel.—A shrapnel shell is filled with bullets, and the head is lightly attached. The bursting charge is only required to blow off the head and liberate the bullets. Little power is necessary, but it must act instantaneously. A charge of gunpowder in a cup at the base of the shell is found to answer best.

As time-fuze composition.—The timing rings in fuzes, which regulate the moment of the burst, are filled with compressed powder. Under atmospheric pressure, this burns with great regularity. Gunpowder is also used for blank charges, for land mines, and has many other minor uses, where certainty of action is of more importance than power.

Picric powder (also called Brugère's powder) is a mixture of finely divided ammonium picrate with potassium nitrate, in the proportions of 43 to 57. It can be detonated by moderate percussion. It is difficult to ignite, but a flame will do it, and it requires good tamping to obtain the full effect. It has about twice the power of gunpowder.

When exploded in a confined space the explosion may proceed to detonation, and the wave set up will extend to picric acid. For this reason picric powder, both in powder form and compressed pellets, is used to detonate lyddite shells.

A less sensitive modification of picric powder, in which the potassium nitrate is replaced by ammonium nitrate, is used for charging bombs, etc.

Tonite.—This is a mixture of about equal weights of barium nitrate and guncotton. It is a powerful high explosive, with great shattering power, and was formerly much used as a blasting powder. It is used in sound-signal rockets.

Smoke compositions.—There are many, some depending on the incomplete combustion of carbonaceous matters. Others consist of nitrates mixed with aluminium or zinc, the oxide of the metal forming a white cloud. Packets are introduced into some high explosive shells to show the position of the burst.

Mixtures of nitrates and chlorates are used in various compositions for flares, and will be referred to later.

INDUSTRIES AFTER THE WAR.

IV.—Textiles.

Of the four Departmental Committees appointed by the Board of Trade to consider the post-war position of our more important national industries, the one which dealt with textiles had probably the most arduous labours; its report certainly is the most extensive of the whole. Upwards of 200 witnesses were orally examined, and nearly as many firms sent written replies to the Committee's *questionnaires*. The trades under consideration

were Cotton, Wool, Silk, Linen, Jute, Lace and Embroidery, Hosiery and Fabric Gloves. The "key" industries, *i.e.* synthetic dyes and knitting needles, for supplies of which, previous to the war, we were entirely or mainly dependent upon foreign countries, also formed part of this very exhaustive inquiry. The Blue-book [Cd. 9070] containing the results of the investigation runs to 130 pages, and is deserving of careful study. The arrangement of the large amount of valuable matter brought together is excellent.

Cotton.

This, perhaps the most powerful of our manufactures and the largest of the world's textile industries, has the lion's share of the report. To assess the exact ratio between cotton production for home use and for export is somewhat difficult, but it is estimated that about 80 per cent. of these fabrics are shipped abroad. The yarn markets are not identical with those for piece-goods. The former fall into two groups—the countries wanting fine counts (spun from raw material of Sea Island, Egypt, Peru, and the West Indies), viz., Germany, the Netherlands, the United States, France, Switzerland, Austria, Italy, Russia and Sweden; and the countries needing the coarser counts (spun from American and Indian cotton)—India, Turkey, the Balkans and South America. Before the war the trade with Germany exceeded all others in importance, and in 1913 was of the value of £5,141,022. The Germans used British fine yarns to make laces, hosiery, fabric gloves, trimmings and velvets for sale in foreign countries, especially Great Britain and the Dominions. Indeed, the outstanding feature of the yarn trade is, or rather was, the extremely large proportion disposed of to enemy countries. This trade, the Committee says, will probably suffer some dislocation after the war, and compensatory markets will have to be secured. At present these are being found in France and neutral countries. In the future the Germans will doubtless increase their fine spinning, so as to be independent of British sources of supply. On the other hand, more lace and hosiery machines and looms are likely to be provided here to manufacture articles previously "made in Germany."

The principal markets for piece-goods are grouped as follows: (*a*) British India and Far East, (*b*) Near East, Egypt, Levant and Balkans, (*c*) Central and South America, (*d*) Continent and United States, (*e*) Africa. The first group absorbs 56 per cent. of the total export, India's share alone being 36 per cent., or roughly £35,000,000 out of £55,000,000. China takes 12 per cent., the Dutch East Indies 4 per cent., the Straits Settlements 2 per cent. and Japan 1 per cent. The respective values of the other groups are—(*b*) £8,417,981, (*c*) £7,899,852, (*d*) £10,400,000. The chief outlets among the Allies in 1913 were: Belgium (£744,801), France (£376,973), Italy (£287,077), Portugal (£125,551), and Russia (£139,813). The report, it should be observed, was written before America entered the war. The value of English piece-goods exported to the United States in 1913 was £1,572,000. Subsequently the prosperity of American and neutral markets caused larger shipments, those to the United States rising to £2,642,592. The increase of exports to the French colonies in Africa has been very marked within the past four years. As supplies from France were not procurable, British goods obtained a footing in markets until then barred by tariffs to our producers. In 1916 the shipments to French Africa realised £6,359,545, of which Morocco's share was £1,178,861.

The Committee views with some concern the part taken by German merchants in the distribution of British textiles in China, and in many other markets prior to the war. Every effort, it is urged, should be made by exporters, either on their own account or in co-operation with merchants on the spot, to secure and retain after the war as great a proportion as possible of the legitimate business formerly handled by German distributing houses. "The present time offers an excellent opportunity. In Hong Kong and Singapore the German houses have been closed and placed in liquidation, and in China and South America they have lost ground considerably. In these circumstances it seems to be desirable that British merchants should either open branches in these markets, or co-operate more closely with existing houses on the spot, or finance young and energetic men with knowledge of the markets and encourage them to open businesses on their own account." The latter proposal seems particularly worthy of consideration as a possible measure of reconstruction. The Committee is informed that the number of British merchant houses which have been established in these markets during the past ten or twelve years is remarkably small.

Examining the vitally-important problem of raw cotton, the Committee shows that throughout the world in recent years there has been a distinct tendency for the demand to exceed the supply; consumption has, in fact, been limited by the available resources, and this state of things, it is believed, will become worse unless special steps are taken to stimulate production. Of a total output of twenty-six million bales the United States in 1912-13 produced fourteen million. Practically none of the Chinese or Russian crop is procurable by the rest of the world. A large proportion of the Indian crop and much of the comparatively small quantities grown in South America and Mexico are also retained for home use. Our dependence upon the United States is all the greater because so much of our spinning machinery is specially adapted to American cotton. About 75 per cent. of the raw material Lancashire consumes comes from the United States. Then, again, American mills are using more and more of the American crop, and the possibility of that crop continuing to expand indefinitely is doubted by many judges.

The report suggests that the British Empire can, and ought to, be made self-sufficing in this matter. Of the possible areas—India, Egypt and the Sudan, the African Colonies and Protectorates —the Committee considers that, for reasons it mentions, India offers the best opportunity for any considerable increase in the near future. Hitherto difficulty has been experienced in securing an adequate price for improved types of Indian cotton owing to the grower not being in direct touch with the world's markets. Better stapled cotton usually gives a smaller yield, is more susceptible to variations in climatic conditions, and requires more care and trouble in cultivation and picking. Naturally the *ryot* is not disposed to grow the better qualities when he is not sure of a better price. Memoranda received by the Committee from the India Office set forth the endeavours of the Supreme and Provincial Governments to improve both the quantity and the quality of the cotton grown. The Committee thinks that an extension of these endeavours might be made with advantage along lines it indicates, but realises that this can hardly be done under the present conditions. In the circumstances it merely recommends that the staff of the Agricultural Department be largely increased throughout the cotton-growing parts, and that some permanent organisation, representing both British and Indian spinners, should co-operate with the Government of India "in securing an adequate price for cotton of improved cleanliness, length, and fineness, until such time as fair and adequate prices can be obtained through the usual commercial channels."

Approximately one-fourth of the British spinning industry relies on Egypt for raw cotton. The Committee considers that the distribution of the Egyptian crop should, during the period of reconstruction, be strictly controlled by the Khedivial Government upon clearly defined lines, so that the requirements of Great Britain and her Allies may be fully safeguarded. In the three years before the war the United Kingdom and her Allies, not including America, received 67 per cent. The proportion of the United States was 11·75. While in Egypt proper, except, perhaps, in the northern part of the Nile Delta, any considerable increase of acreage seems to be doubtful, it is agreed that the Sudan offers a promising field if the various irrigation schemes, postponed on account of the war, are proceeded with. The adoption of a comprehensive plan for the best apportionment of the water available from the Nile is recommended.

With regard to the African Colonies and Protectorates, it is pointed out that though they are well adapted for growing the kind of cotton Lancashire seeks, years of sustained effort must pass before they become a serious factor.

The report strongly urges the immediate appointment of a committee, representing all the interests affected at home and abroad, for the purpose of investigating the question of increasing the Empire's cotton supply. The Committee does not desire that this committee should be invested with any powers of control, and says that in regard to the extent and mode of development the discretion of the various Governments concerned must necessarily remain unfettered.

(*To be continued.*)

TEA INDUSTRY OF FRENCH INDO-CHINA.

A native tea plant (*Thea viridis*), closely related to the Chinese variety, has been cultivated by the natives of Indo-China for many years, and has been exported in considerable quantities since 1900. Europeans have been interested in tea plantations in Tonkin and Central Annam for some time with varying degrees of success, but it is only within quite recent years that native tea has begun to rank among the principal exports of the Saigon district.

The principal tea region of Indo-China is in the province of Quang-Nam, in central Annam. The native village of Tam-ky is the most important tea centre, and most of the exported tea is shipped from Tourane. The provinces of Phu-Tho and Bac-Giang are the chief tea regions of Tonkin. During recent years most of the Tonkin product has been sent to Tourane for preparation. The remainder is exported from Haiphong. An important part of the Tonkin product, consisting of tea flowers formed by the buds, is highly prized by both natives and Europeans. Practically the entire product that is shipped from Tourane goes to France, where it is mixed with Ceylon and other teas. Tonkin tea shipped from Haiphong goes mainly to foreign countries. The exports of native tea from Tonkin and Annam in recent years have been as follows:—

	Tonkin. Kilos.	Annam. Kilos.	Total. Kilos.
1913 . .	79,851	290,062	369,913
1914 . .	121,046	420,173	541,219
1915 . .	67,105	891,164	958,269
1916 . .	106,742	814,507	921,249

In nearly all parts of Indo-China the natives produce tea for their own use, and some tea is sold in the native market for local consumption. The Chinese inhabitants of Cholon, Faifo, and other parts of Indo-China use a little native tea, but its use has not extended in any degree to the European inhabitants. The decline of tea imports since 1914, except probably in Annam, can be fully accounted for by the decrease in the European population since the beginning of the war.

During the past few years tea has become one of the most important articles of export from the Saigon district. The Customs value of the tea exported from Annam during the years 1914-16 was £31,900, £60,200, and £65,400 respectively. The higher value for the 1916 product was due to a change in Customs value corresponding to an improvement in quality. The price of native tea

is keeping pace with the quality, and it is likely, writes the United States Consul at Saigon, that it will hold the rank it has gained among the exports of the district. The fact that Europeans are becoming interested in tea plantations is having a good effect on the methods of cultivation. Another need is an improvement in methods of preparation. The modern installations established by the leading exporters are doing much to remedy these conditions, but it will be some time before all the tea of Indo-China is properly prepared.

The fact that the Annam and Tonkin tea imported into France loses its identity, and is sold under another name, is a misfortune for the local industry. The tea of Indo-China is said to be richer in thein and poorer in tannin than that of India or China. With better methods of preparation being developed, a movement is on foot to launch Annam and Tonkin tea on the French market under its own name. The result is expected to be beneficial.

GENERAL NOTES.

Landing Fields for Aviators in America.—The provision of a chain of landing fields for aviators stretching across the United States is progressing steadily, according to the *Engineer*. In some States landing fields have already been provided, equipped to furnish oil and petrol at intervals of 100 miles. It is planned to have the fields also equipped to furnish shelter, machine shop facilities, maps, charts, and barometer and thermometer ratings to the pilots. Lines of such landing fields have been established in the States of New York, Pennsylvania, Ohio, Illinois, Texas, Georgia, California and others.

South African Timber.—Speaking before the South African Association on the subject of "Timber Supplies and Forestry in the Union," Mr. C. E. Legat, Chief Conservator of Forests for the Union of South Africa, said that in 1913, the last normal year, the importation of timber into the Union amounted to 17½ million cubic feet, worth 1¼ million pounds sterling. Ninety per cent. of the importation was coniferous wood. Though the area of forest reserves in the Union was considerably over 1,000,000 morgen, the area of actual forest was only between 200,000 and 250,000 morgen. This forest produced only one timber, viz., yellow-wood. It was computed that the annual output of yellow-wood would not amount to much more than 1¼ million cubic feet. That amount was only a fraction of the Union's present-day requirements, and in fifty years' time these requirements could be expected to be double, as progress in industry was invariably followed by increased timber consumption. Unless, therefore, South Africa was for ever to remain dependent on other countries for its timber, it was essential that afforestation should be undertaken on a large scale. Neglect of afforestation would result in the Union being forced to compete for the world's surplus timber, and to buy, whatever price might be demanded. Prices were likely to rise steadily, for, in spite of the use of iron, steel, and concrete, the world's consumption of timber was increasing without any corresponding increase of forest. In conclusion it was announced that recently the Government had approved of the initiation of certain schemes which, when ultimately completed, would result in the afforestation of approximately 64,000 acres.

Wood and Peat for Gas-making in Denmark.—The carbonisation of wood and peat for gas-making in Denmark was, says the *Journal für Gasbeleuchtung*, necessitated by the shortage of coal in 1917. Horizontal hand-fired retorts were used; and a certain amount of coal was carbonised, but separately from the substitutes. Trouble occurred owing to accumulations of pitch in the hydraulic main; and on distribution of the gas there was an increase of trouble due to naphthalene stoppages. The yield of ammonia was small; but, the admixture of a proportion of coal-gas sufficed to neutralise the acetic acid present. The air supply of gas appliances required adjustment; but, apart from an increased consumption, the gas behaved satisfactorily in most of its applications. The pitch from wood and peat was valueless; but the brown tar found a ready market. The wood charcoal proved to be well adapted for use in suction-gas producers. Peat charcoal, however, was less satisfactory, as much of it was small, and had to to be employed as an indifferent domestic and industrial fuel.

Shipbuilding in India.—The Indian Munit[illegible] Board announces that in respect of wooden sai[illegible] vessels which may be provided with auxilia[illegible] engines the Government of India will assist constructing firms. An undertaking is given by the British Shipping Controller that in the event of any vessel built in India being required by Government special rates will be paid. The Indian Shipping Controller will help in the way of technical advice and plans, and timber will be supplied by the Madras, Bombay and Bengal Forest Departments at moderate rates and on easy terms of payment, while in Burma the local Deputy Controller of Timber Supplies will assist in negotiations for timber with the firms holding forest leases there. Help will also be afforded in procuring the importation of canvas for sails, as well as other accessories for wooden sailing ships, which it may be necessary to obtain from abroad. Government will ordinarily grant a licence for the flotation of any shipbuilding company which has a fair prospect of being able to commence operations in a reasonable time.

OF THE
ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,438. VOL. LXVI.

FRIDAY, OCTOBER 11, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

MILITARY EXPLOSIVES OF TO-DAY.

By J. Young, O.B.E., A.R.C.S., F.C.S.,
Chief Instructor in Science, Royal Military Academy, Woolwich.

Lecture II.—Delivered April 15*th*, 1918.

CHLORATE EXPLOSIVE MIXTURES.

In the first lecture I dealt with the various nitrate mixtures. Next in importance to these are the chlorate mixtures.

Potassium chlorate ($KClO_3$) is a non-deliquescent salt, which, on heating, gives off 39·1 per cent. of its weight of oxygen. It also gives out heat during the decomposition, 1 gram yielding 8·74 calories, and is, therefore, an explosive in itself. It is much used in the preparation of oxygen in laboratories, and if heated too rapidly may explode with great force, as many have found.

When mixed with combustibles it forms explosives much more powerful than nitrate mixtures, but also much more sensitive and dangerous to handle. The discoverer Bertholet, in 1788, tried to use it to replace saltpetre in gunpowder, but at the first attempt the mill promptly blew up and killed some of a company specially invited to see the process.

The sensitiveness may be illustrated by mixing a little powdered chlorate with sulphur; it detonates sharply when struck on an anvil. Similarly with black antimony sulphide, and also with many other combustibles. Chlorate mixtures of this kind are now mostly used for purposes where sensitiveness is a necessity, as in percussion caps, friction igniters, etc.

The mixing of chlorate with combustibles of any kind in the dry state is always dangerous. When done, the substances should be ground separately in clean mortars, and mixed by sifting so as to avoid undue friction.

Potassium perchlorate ($KClO_4$) contains a greater percentage of oxygen, 46·2 per cent., but is a much more stable substance. Heat is absorbed in its decomposition, and mixtures containing it are less sensitive than plain chlorate mixtures.

Ammonium perchlorate (NH_4ClO_4) is still less sensitive, and is now much used in explosive mixtures. With plain combustibles it gives off hydrochloric acid gas when exploded, and as this is very objectionable with mining mixtures a proportion of sodium nitrate is added to convert the HCl into sodium chloride ($NaCl$) which is harmless.

Potassium chlorate and sugar.—Many of the attempts which have been made to reduce the sensitiveness of chlorate mixtures have taken the form of using some imperfect combustible to mix with the chlorate, and sugar has often been proposed. A mixture of two parts of $KClO_3$ with one of sugar is as good as most. It is much less sensitive than a mixture of chlorate with carbon and sulphur, and has about twice the power of gunpowder. But it is still too sensitive and violent in its action. It can be exploded by contact with flame, by moderate percussion on an anvil, and also by contact with strong sulphuric acid. Use has been made of these properties in automatic igniters for other charges. It makes a good flare, but is not a military explosive.

Friction composition.—Many variations are used, but the following gives the proportions of a typical mixture:—

Potassium Chlorate . . .	12
Antimony Sulphide (black) .	12
Sulphur	1

The substances are ground separately, mixed into a paste with spirit containing a little shellac, and formed into pellets, which are dried. Sometimes one part of ground glass is added to make it more sensitive. Sometimes gunpowder is added.

To show its properties apply a flame to a little; it ignites instantly, and the flash is very efficient for igniting other explosives.

Put a little on an anvil and strike sharply. It detonates with moderate percussion.

Put a little on the anvil and rub hard with a hammer face; it explodes sharply.

For many years this has been used in friction tubes for firing heavy guns, and is still used. The friction tube is a copper tube filled with gunpowder which is inserted into the breech of the gun. At the outer end is a cross tube, and in this is a kind of copper rasp or twisted wire. Pellets of the friction composition are pressed closely in contact with the "friction bar," so that when it is pulled out sharply by the gunner the composition explodes and ignites the gunpowder, which sends the flash that ignites the cartridge.

Igniters for safety fuse are made on the same principle. The fuse is tipped with a friction composition which, when rubbed with a prepared surface, flashes off and ignites the fuse.

Equal weights of amorphous phosphorus and chlorate make a most sensitive and powerful explosive, formerly used in an Armstrong shell fuse. They are dangerous to mix dry, but can be mixed safely if moistened with methylated spirit, and then separated into very small portions. The mixture explodes with very gentle percussion or friction. It is used in toy caps.

The use of friction compositions is well illustrated by a box of safety matches. The match head is tipped with friction composition diluted with glue, and can be ignited by strong friction or by percussion. The box is coated with a little amorphous phosphorus and ground glass. A little friction between the two suffices to bring about ignition.

Flash compositions.—A mixture of two parts of potassium chlorate and one part of magnesium or aluminium powder, gives a powerful flash when ignited. The light is very actinic, and suitable for taking photographs. Either mixture can be exploded by percussion, that with aluminium being specially sensitive and powerful, as shown by striking a little on an anvil, and dangerous to handle in quantity.

Mixtures with potassium perchlorate are much safer, and quite effective. One such mixture contains three parts of perchlorate with two parts of magnesium powder. It gives a high temperature, and is used for igniting thermit and other materials in bombs. It also requires careful handling.

Chlorate Mining Explosives.

All of the above-mentioned chlorate explosives are much too sensitive for use in large quantities in military operations. But a discovery made by Street in 1897, that if the chlorate mixture contained oils or fats its sensitiveness was greatly decreased, initiated an entirely new set of blasting explosives. The first, and amongst the best, are the Cheddites, made at Chedde in France. They are mixtures of potassium or sodium chlorate with a nitro compound, and castor oil. A typical cheddite has the composition:—

Potassium Chlorate . . .	79
Di-nitro-toluene	15
Nitro-naphthalene . . .	1
Castor Oil	5

Cheddites are much used as blasting explosives. Potassium perchlorate is used in a number of similar mixtures of which Permonite is an example. Some also contain nitroglycerine.

Blastine.—This is the most important military chlorate explosive, and vast quantities have been used in the present war. There are several varieties, but a typical military blastine has the following composition:—

Ammonium Perchlorate . .	60
Sodium Nitrate	22
Tri-nitro-toluene	11
Paraffin wax	7

It is made in the form of a soft, yellowish, granular substance, which can easily be compressed. It is not very sensitive, but can be detonated by a moderate blow on an anvil. In practical tests, rifle bullets have been fired through cartridges without exploding them, but it can hardly be considered safe under such a test, especially if the cartridge had a hard backing. It ignites easily and burns fiercely with a hot flame. In practice it is detonated by a fulminate detonator, and is a powerful high explosive, about equal to ammonal. Velocity of detonation, over 4,000 metres per second.

Blastine is extensively used for military mines and for charging bombs and grenades. The products of detonation do not contain any hydrochloric acid gas, and are not poisonous.

Permite.—This is a mixture intermediate between ammonal and blastine, and may be looked on as ammonal in which the expensive aluminium is replaced by zinc powder, the consequent diminution in power being compensated for by using ammonium perchlorate instead of the

nitrate. It is made in several varieties. One has the following composition:—

Ammonium Perchlorate . .	82
Zinc Dust	10
Vaseline	5
Asphaltum Varnish . . .	3

Some varieties have sulphur, and methyl alcohol and benzene as solvents.

It is used for the same purposes as blastine, and has about the same power. It is more sensitive to percussion. In form it is a greyish-brown powder.

All of the chlorate explosives require fulminate detonators, and for this reason, besides being too sensitive, are unsuitable for use as a high explosive shell filling. Rate of detonation, 4,000 to 5,000 metres per second.

Mixtures of ammonium perchlorate and paraffin wax with combustibles such as aluminium powder or wood meal are also used, and are powerful high explosives.

Ammonium perchlorate explosives, like the corresponding nitrate mixtures, detonate best when in a porous form. Like these, too, they tend to set into a dense mass when stored, especially if exposed to high atmospheric temperature, and in that condition are very insensitive, and may fail to detonate. They should not be exposed to direct sun rays.

Some Miscellaneous Mixtures.

Thermit, now an important munition of war, is in a class by itself. It is a mixture of about six parts of iron oxide with one part of aluminium powder, highly compressed. It has a very high ignition point, and requires a priming of a mixture of magnesium powder with barium peroxide or potassium perchlorate. When once ignited, a fierce reaction takes place. The aluminium abstracts the oxygen from the iron oxide, liberating metallic iron and so much heat that the temperature is in the neighbourhood of 5,000° C., one of the hottest things on earth. It is used for charging incendiary bombs, and sometimes in a kind of shrapnel. A small explosive charge scatters the contents, which rain down bits of blazing iron, which will instantly set fire to anything capable of burning.

Coloured lights and flares.—These are mixtures of metallic chlorates and nitrates with combustible matter, and sometimes inert metallic salts. Shellac is one of the best combustibles, and sometimes sugar is used. Chlorates make the most energetic mixtures, but 50 per cent. or so of nitrate is usually added to make the mixture slower in action and safer to handle. The colour of the flame depends on the metal used. Thus:—

Barium	compounds	give	green.
Strontium	,,	,,	red.
Copper	,,	,,	blue.
Sodium	,,	,,	yellow, etc.

Many formulæ are in use; the following are examples:—

Green light—	
Barium Chlorate and Nitrate	80 parts.
Shellac (or milk sugar) . .	20 ,,
Red light—	
Strontium Nitrate and Potassium Chlorate	84 parts.
Shellac	16 ,,

Magnesium lights.—Mixtures used for illuminating purposes in rockets or star shells consist of magnesium powder mixed with chlorates and nitrates, a little oil or wax being incorporated to slow the action and make it burn a longer time. 63 parts of a mixture of potassium chlorate and barium nitrate, 35 of magnesium powder, and 2 of boiled linseed oil gives a good lasting light.

The Nitrocelluloses.

As early as 1832 Bracannot discovered that the action of nitric acid on starch and woody fibres converted them into highly inflammable substances. In 1838 Pelouze extended the experiments to paper, linen, and cotton. In 1846 Schönbein, the discoverer of ozone, used concentrated nitric acid and cotton-wool, and called the resulting substance guncotton. A little later, sulphuric acid was added to the nitric, and this mixture has been used ever since.

Schönbein gave demonstrations of the new explosive in England in 1846. The value of an explosive which was several times more powerful than gunpowder, and quite smokeless, was immediately recognised. Its manufacture was started the same year in England at Faversham, and also in France; a little later, in Austria.

Next ensued a series of disastrous explosions which could not be accounted for. The manufacture was stopped everywhere as being too dangerous.

About 1863 the late Sir Frederick Abel conducted a series of experiments at the Waltham Abbey factory, which explained the cause of the explosions, and also how the substance could be made and kept safely. The researches were

published in 1866-67. Briefly, they amounted to this:—

Cotton, in its microscopic structure, is made up of minute capillary tubes. During the process of nitration the tubes become filled with acid, and, as they are practically waterproof, the elimination of the acid by washing is a difficult matter, the amount of washing usually given being quite insufficient. Later, it was shown that some sulphuric acid remains chemically combined with the cellulose.

In stored guncotton both free and combined acids set up a decomposition, with evolution of heat. The rise of temperature accelerates the rate, and when large masses are stored the temperature may at last reach the explosion point, which it did in many cases.

Abel showed that to eliminate the acid a prolonged series of boilings was necessary, these acting, partly mechanically by dissolving the acid, and partly chemically by decomposing the sulphate. Pulping the guncotton, by dividing it into infinitesimal fragments, facilitates the process, besides making it more easily manipulated into suitable forms for use.

The cotton used must be nearly pure cellulose. The natural impurities associated with it, which are of a fatty or resinous nature, form unstable nitro-compounds, which hasten the decomposition of the whole.

Finally, as the guncotton still contains traces of free or combined acid, a preservative capable of combining with the products of decomposition must be incorporated with it. The guncotton will then be fairly stable, but still it has a limited life, the length of which depends on the temperature at which it is stored.

Acting on these principles, Abel established a process for the manufacture of guncotton, which, with some modifications, is carried out to this day. There are other forms of nitrocellulose which, with guncotton, form the most important military explosives of to-day, and are the basis of all smokeless powders.

Cellulose has the empirical formula $C_6H_{10}O_5$, and belongs to the class of bodies called carbohydrates, which includes starch, sugar, and gums. Any one of these will produce an explosive compound when treated with nitric acid. Cotton is the purest natural form of cellulose, and when treated with dilute boiling caustic soda, and chlorine, and afterwards well washed, is almost pure cellulose. Wood and other vegetable fibres contain large percentages of modified celluloses, such as lignose, oxycellulose, pectoses, and so on. As these are more chemically reactive than pure cellulose, they can be removed by reagents, and most of them are removed in the process of preparing wood pulp for papermaking. It has been shown that by a drastic treatment 40 per cent. of good cellulose can be obtained from a suitable wood, and from this a stable nitrocellulose can be obtained, although not quite so powerful as that from cotton. It is extremely probable that most of the German cellulose is now obtained from this source.

Action of nitric acid on cellulose.—When cellulose is acted on by a mixture of nitric and sulphuric acids containing water, either a mono-, di-, or tri-nitrate may be formed, depending on the proportions of the acids and water present. Thus:—

(1)
$$\underset{\text{Cellulose}}{C_6H_{10}O_5} + \underset{\text{Nitric acid}}{3HNO_3} + \underset{\text{Sulphuric}}{nH_2SO_4} = \underset{\text{Tri-nitrate}}{C_6H_7O_2(NO_3)_3} + nH_2SO_4{\cdot}3H_2O.$$

(2)
$$C_6H_{10}O_5 + 2HNO_3 + nH_2SO_4 = \underset{\text{Di-nitrate}}{C_6H_8O_3(NO_3)_2} + nH_2SO_4{\cdot}2H_2O.$$

Similarly, for the mono-nitrate. The H_2SO_4 combines with the water liberated in the reaction, and serves to keep the concentration constant (within limits), but it also probably plays a much more important part.

The actual reactions which take place are certainly much more complicated than as represented, and although much research has been devoted to the problem it is still obscure. Theoretically—

	Per cent.
Tri-nitrocellulose should contain	14·14 of N.
Di- ,, ,, ,,	11·12 ,,
Mono- ,, ,, ,,	6·77 ,,

No one of these has been prepared pure. 13·92 per cent. of nitrogen has been obtained, but the substance was not stable. 13·5 per cent. appears to be the limit for a stable compound, and a good guncotton contains about 13 per cent. of nitrogen. Attempts have been made to account for the varying percentages of nitrogen by multiplying the formula of cellulose and assuming a large number of nitrates, but the results are not satisfactory.

Soluble and insoluble nitrocelluloses.—Some forms of nitrocellulose, especially the greater part of the highly nitrated guncotton, are insoluble in a mixture of alcohol and ether, while other forms are soluble. The lower nitrates are most soluble. It was therefore assumed that the tri-nitrate was the insoluble form, and that the lower nitrates were soluble. As 10-12 per cent. of guncotton was soluble, it

was assumed to be a mixture of insoluble tri-nitro with 10–12 per cent. of di-nitro. As the power of explosion of guncotton depends on the extent of nitration, for this reason, as well as the belief that the soluble variety was unstable, every effort was made to keep down the percentage of solubility.

But we now know that the solubility in alcohol-ether is largely a matter of temperature of nitration. The higher the temperature, up to about 40° C., the greater the solubility. The amount of water present is also a factor. Nitro-cellulose, containing 12·5 per cent. of nitrogen and soluble in alcohol-ether, or at least completely gelatinised by it, is now made on an enormous scale, and constitutes 99·5 per cent. of nitrocellulose smokeless powders, as well as being used in the new cordite.

All kinds of nitrated cotton retain their original structure and appearance, except that they are a little harsher to the touch. They can be spun into yarn or even cloth. When dry, nitrated cotton is very inflammable, and burns rapidly when uncompressed. It can be detonated by percussion, and easily by fulminate.

Manufacture of guncotton.—Practically the only improvement on the original Abel process is the use of the "displacement apparatus" for nitration, instead of the original earthenware pots, where the cotton was allowed to soak in the acid mixture. This was invented by Nathan and Thompson, of Waltham Abbey, and is now generally used.

The figure shows a section of one pan, of which four form a set.

The pan is 3 ft. 6 in. in diameter by 10 in. deep, and is made of earthenware or acid-resisting iron. By means of valves, the outlet can be made to communicate either with an acid supply, a waste acid receptacle, or a drain.

The acid mixture found to be best consists of three parts by weight or ordinary pure concentrated sulphuric acid with one part of nitric. The mixture contains 8 per cent. of water. The details of the process of manufacture are given in any treatise on explosives. The following is an outline of the Waltham Abbey procedure :—

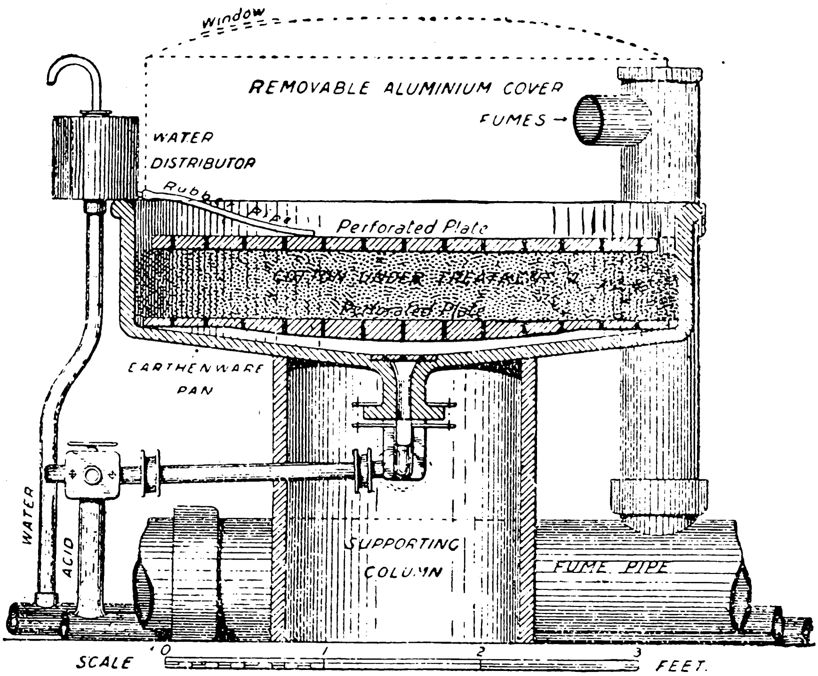

FIG. 2.—GUNCOTTON APPARATUS.—DISPLACEMENT PROCESS.

About 650 lb. of the cooled acid mixture is admitted to the pan, and 20 lb. of the purified and prepared dry cotton immersed. A perforated aluminium plate is then put on top, and water run on to it to act as a seal and prevent the escape of fumes.

After $2\frac{1}{2}$ hours the acid is run off at the bottom slowly, and water run in on top at the same rate, so that the water displaces the acid, thus giving the name to the process. In $3\frac{1}{2}$ hours the nitrated cotton is free from surface

acid, and ready for purification. The advantages over the old process are that it gives a better yield of a more uniform and stable guncotton, besides saving time and labour, and involving less exposure of the workers to acid fumes.

The guncotton is next boiled in great vats which hold nearly a ton of it. There are ten boilings lasting fifty hours, starting with long boilings of twelve hours, and ending with short ones of two hours. It is next pulped in a paper-maker's beater, which cuts it into infinitesimal fragments. The pulp is washed in several changes of water.

When required for the manufacture of cordite, the pure pulp is measured into moulds and subjected to gentle pressure, about 34 lb. per sq. in., which removes much of the water and leaves the guncotton in primers firm enough to be handled. These are taken away to be dried.

When required for use as a demolition agent, a mixture of caustic soda, lime water, and whiting is added to the pulp, sufficient to leave 1 to 2 per cent. in the finished article to act as preservative. The pulp is then moulded and pressed as before, but receives a final pressure of 5 to 6 tons per sq. in., which converts it into slabs. For land service, 15 oz. slabs are the standard, and they are moulded with a central conical hole to take a 1 oz. primer. They are dipped in a solution of carbolic acid and caustic soda to prevent mould, and packed in metal cases which are hermetically sealed. They contain about 17 per cent. of water.

The primers are moulded and pressed in the same way as the slabs, with a central hole to take the detonator. Next, they are dried down to 1 to 2 per cent. of moisture, then dipped in acetone to dissolve the surface and give it a waterproof glaze. They are packed very carefully in special tin tubes, each of which contains one dozen. One ounce primers are the standard for land service. For the naval service slabs and primers of different weights are used.

Slabs of wet guncotton constitute the safest and one of the most effective demolition agents, and remain the standard of the R.E. With more than 13 per cent. of water guncotton is quite incombustible, and very difficult to detonate except by large charges of fulminate, or an ordinary detonator and a dry primer. For example, during the present war an 8-in. shell, detonated in a waggon-load of wet guncotton, failed to explode it. The primers and detonators are carried separately. When detonated in good contact with the object to be demolished it produces intense cutting effect, even untamped, although there is little advantage in increasing the depth of charge above two or three slabs. With large charges tamping is an advantage. A guncotton slab will cut through its own thickness of iron; a necklace of primers tied round a good sized tree will cut it down. The velocity of detonation is about 5,600 metres per second.

As guncotton contains insufficient oxygen for its complete combustion, the gases contain 30 to 45 per cent. of carbon monoxide, and 15 to 20 per cent. of hydrogen. They are both inflammable and poisonous, and for this reason alone guncotton is unsuitable for mining.

In practice the slabs are placed or secured in intimate contact with the object to be demolished, and with one another. A primer is inserted in one slab, and a detonator in the primer. A No. 8 detonator is used when firing is to be done by fuse, safety or instantaneous; a No. 13 electric detonator when the firing is done electrically, which is the best method but takes more time.

The firing of a charge I illustrate by firing a detonator in a safety iron box. Military mines are fired in the same way.

Guncotton was formerly used exclusively for torpedo warheads, marine mines, etc., but has now been largely replaced by T.N.T., and ammonium nitrate and chlorate mixtures.

Guncotton in store.—Like all varieties of nitrocellulose, guncotton decomposes on keeping, and the rate increases with the temperature. Hence it should be kept as cool as possible, and never exposed to the direct rays of the sun. In temperate climates it should be good for twenty years at least, but has a much shorter life in the tropics.

When guncotton shows signs of acidity, or brown fumes are seen, it shows that decomposition has proceeded far, and it is unsafe. When it dries it can be rewetted without any deterioration. It can absorb 30 per cent. of water, but is then too insensitive. In the best condition it should just ooze moisture when pressed by the finger—15 to 17 per cent.

High-nitrated soluble nitrocellulose. — The manufacture of this substance is carried out in much the same way as that of guncotton, the only difference being in the composition of the acid mixture and the temperature of nitration. In one method the acids consist of a mixture of equal volumes of concentrated sulphuric and nitric acid, and the nitration is carried out at 40° C. for half an hour. The product is washed and stabilised as with guncotton, and contains

12·4 per cent. of nitrogen. It is completely gelatinised by an alcohol-ether mixture.

In the manufacture of American nitrocellulose the acids have the following composition:—

Sulphuric Acid	63
Nitric Acid	22
Water	15

The nitration is carried out at 30° to 32° C. in an apparatus similar to that used in the Waltham Abbey plant, and the product is stabilised in much the same way. It contains 12·5 to 12·7 per cent. of nitrogen, and is completely gelatinised by alcohol-ether.

Contrary to former beliefs, this soluble nitrocellulose appears to be as stable as guncotton, but not quite so powerful.

Collodion cotton (also called pyroxylin).—This variety is made by using a still weaker acid mixture, and nitrating at a still higher temperature. In one formula used the acid contains 35·5 per cent. of nitric acid, 44·5 per cent. of sulphuric, and 20 per cent. of water by weight. The nitration takes place at a temperature of 55° C., and lasts half an hour. The product is well washed, but not boiled or pulped.

It contains about 11 per cent. of nitrogen, and dissolves readily in an alcohol-ether mixture (about 1 part in 30 of the mixture by weight) forming a clear solution called collodion. This leaves a perfectly transparent film when poured on a surface and allowed to evaporate. It is much used in photography, and in surgery for covering wounds. Collodion cotton dissolved in camphor forms celluloid. Dissolved in nitroglycerine it forms blasting gelatine, a valuable explosive. Mixed with camphor and castor oil collodion is used for coating incandescent mantles to preserve them during transport.

[NOTE.—A mixture of one vol of alcohol with 2 vols of ether is the best solvent for N.C.]

NITROGLYCERINE EXPLOSIVES.

Nitroglycerine was discovered by Sobrero in 1847, and still remains the most powerful explosive in practical use. It is of great military importance, and is a constituent of our standard smokeless powder.

Glycerine ($C_3H_5(OH)_3$) is a constituent of all animal and vegetable fats and oils, which are the only source of supply on the large scale. The various tropical products, palm oil, coconut oil, etc., are sources of glycerine.

When these fats or oils are boiled with caustic soda or potash (lye), they form a mixture of glycerine and soap, and this is probably one of the oldest chemical processes:—

$$\underset{\text{Mutton fat}}{(C_{18}H_{35}O_2)_3C_3H_5} + 3\,\underset{\text{Soda}}{NaOH} = \underset{\text{Glycerine}}{C_3H_5(OH)_3} + \underset{\text{Soap}}{3C_{18}H_{35}O_2Na}.$$

Pure glycerine suitable for the manufacture of explosives is difficult to separate from the soap, so other processes in which the fats are acted on by high pressure steam, or lime, are used, the products being the free fatty acid or a lime soap, and glycerine. Hence, when fats are scarce and glycerine is required, soap is also likely to be scarce. About 10 lb. of fat are required to produce 1 lb. of glycerine.

When glycerine is required for conversion into nitroglycerine it must have a high degree of purity, and specific gravity not less than 1·26. The acid mixture found best for the nitration contains one part of HNO_3, specific gravity 1·5, and 1·7 parts of H_2SO_4 containing 96 per cent. of pure acid, by weight. When one part of glycerine is poured into eight parts of the acid mixture, previously cooled to a temperature of 15° C., and stirred up with it, the nitrating action takes place immediately. On standing a few minutes the nitroglycerine separates and floats on the acids as a clear liquid. The equation representing the action is:—

$$\underset{\text{Glycerine}}{C_3H_5(OH)_3} + \underset{\text{Nitric acid}}{3HNO_3} = \underset{\text{Nitroglycerine}}{C_3H_5(NO_3)_3} + \underset{\text{Water}}{3H_2O}.$$

The sulphuric acid combines with the water liberated by the reaction, and maintains the concentration of HNO_3. It has no further action.

The nitroglycerine may be separated by pouring the whole mixture into a large volume of water, when the acids dissolve and the nitroglycerine, being insoluble, sinks to the bottom. This is the old method and most suitable on the small scale. On the large scale the nitroglycerine is run off from the top through a suitable opening. The operation is perfectly safe if care be taken not to allow the temperature to rise above about 30° C., which necessitates water-bath cooling. Otherwise a decomposition sets in, indicated by the appearance of brown fumes, and may end in a dangerous explosion.

The nitroglycerine only requires to be washed quite free from every trace of acid, and is ready for use. While in contact with acid, it is dangerously sensitive and unstable.

MANUFACTURE ON THE LARGE SCALE.

Figure 3 represents diagrammatically the arrangement of the apparatus used at Waltham Abbey.

Owing to its dangerously sensitive nature, especially when in contact with acid, the greatest possible precautions are taken in the manufacture of nitroglycerine, and accidents are rare. It is made to flow from point to point by gravity during the operations. The temperature is kept low, and watched carefully by means of thermometers immersed in the liquid. All stirring is done by compressed air issuing from perforated pipes laid round the bottom of the vessels, and during nitration the liquid is kept cool by coils of pipes through which cold water is circulated.

A full description of the process of manufacture can be found in the various text-books; briefly, it is as follows:—

The charge of 4,000 lb. of nitrating acid is admitted to the nitrating vessel, and cooled to 16° C. The charge of 500 lb. of glycerine is then injected in fine spray by means of compressed air, and the acids are kept thoroughly agitated by air bubbling through. The temperature is watched, and not allowed to rise above 22° C. If decomposition sets in, as shown by red fumes and a rise of temperature, the whole charge is shot into a drowning tank filled with water underneath the nitrator. This applies to subsequent operations as well.

When the charge has been nitrated, which takes about forty minutes, it is allowed to stand, and the nitroglycerine separates and floats on the acids. Waste acid from another tank is then admitted to the nitrator to raise the level of the liquid, and the nitroglycerine flows off through a side pipe into the pre-wash tank, which is half filled with water. Here it is washed three times with water, and once with water containing some washing soda. It is then run through a gutter into the washing-house proper, where it is washed three times with warm soda-water, and finally with plain water, which leaves it acid-free and practically pure except for a little water.

The water is skimmed off after each washing, and all stirring is done by compressed air.

Finally, it is filtered through flannel bags filled with dry, common salt, which removes all scum and absorbs moisture. The nitroglycerine is then pure and ready for use.

Properties of nitroglycerine.—Nitroglycerine

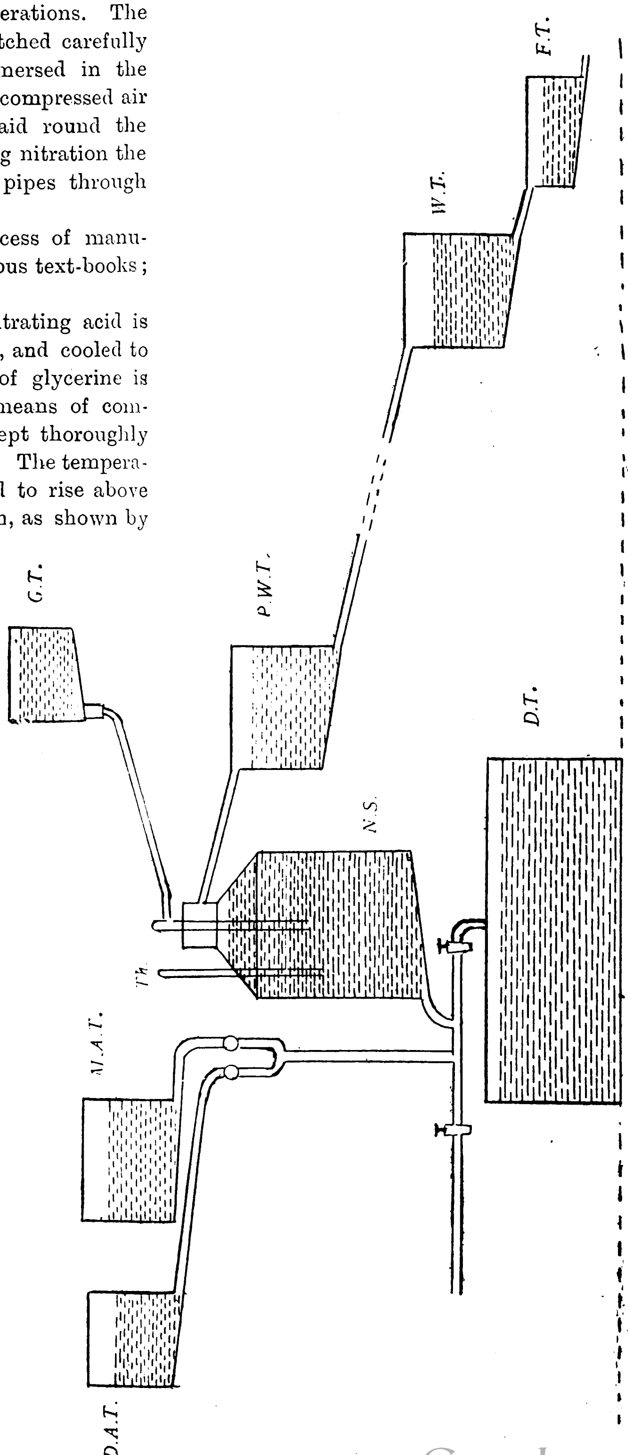

FIG. 3.—NITROGLYCERINE PLANT.—DISPLACEMENT PROCESS.

is a slightly yellowish, transparent liquid, specific gravity 1·6. It is insoluble in water, but dissolves in alcohol, ether, acetone, and many other organic liquids. It is very poisonous, and gives violent headaches even when placed on the skin. It has a powerful action on the heart, and is used as a drug. Many cases of nitroglycerine poisoning occurred in the South African War through soldiers chewing cordite.

The liquid is difficult to ignite, and a taper may be extinguished by dipping it into nitroglycerine; but if a filter paper or some cotton-wool be soaked in the liquid, it burns quietly, but rapidly, with a greenish-edged flame.

To show its explosive properties, put a drop on a filter-paper and strike it with a hammer on an anvil. It detonates with a loud report, and blows the paper to shreds. Put a drop on a smooth metal plate, and heat it fairly rapidly. It gives off vapour at 100° C., boils at about 180° C., but begins to decompose. Red fumes appear, and when the temperature reaches about 180° C. it detonates completely with tremendous effect. When the experiment is successful, a hole is blown in the plate, and the pieces turned right back so as to touch the reverse side.

Fulminate of mercury detonates it completely (about 2 grams will detonate an unlimited amount), with tremendous disruptive effects. A small charge of fulminate sets up an inferior kind of detonation with a velocity of 1,500 to 2,000 metres per second, but with complete detonation the velocity is 7,500 to 8,000 metres per second.

Nitroglycerine is the only explosive compound in use which contains sufficient oxygen for its complete combustion, which explains its great power. The products of detonation contain free oxygen, and are in accordance with the equation:—

$$2C_3H_5(NO_3)_3 = 6CO_2 + 5H_2O + 3N_2 + O + \text{Heat}.$$

It freezes at about 4° C., and forms crystals. In this form it is very sensitive, and merely squeezing crystals between the fingers may explode them; but it does not carry the detonating wave well, and with large charges a great portion may be blown away and escape detonation altogether. This applies to all the nitroglycerine explosives. All require to be thawed before use, which makes them inconvenient for use in cold climates.

Nitroglycerine is the most powerful explosive in use, but in the liquid form is inconvenient and too sensitive to be handled safely. It is now always absorbed in some substance which enables it to be used in a suitable plastic form.

There are two main classes of nitroglycerine explosives in present use.

(1) *The dynamite class.*—The nitroglycerine is absorbed in some porous solid, so that it can be moulded into cartridges. The solid may be an inert substance, or it may be an explosive itself, usually a mixture resembling a primitive gunpowder.

(2) *The blasting gelatine class.*—These have as their basis blasting gelatine, and range from the pure substances to mixtures of mild explosives with varying percentages of it.

Dynamite No. 1, the original dynamite invented by Nobel in 1866, consists of three parts of nitroglycerine absorbed in one part by weight of kieselguhr, a diatomaceous earth. The guhr is calcined and sifted, and is a fine powder free from grit. Up to 2 per cent. of magnesium, sodium, or calcium carbonates are added as preservatives, also ochre to colour it, and sometimes barium sulphate, and similar inert substances. It forms a plastic mass, brown or reddish coloured, and is made into cartridges which are wrapped in parchment paper. It is much less sensitive to percussion than free nitroglycerine, and safer to handle. When ignited in small quantities, it burns fiercely, but does not explode. It is readily detonated by a fulminate detonator, and, as might be expected, its shattering power is about threequarters that of pure nitroglycerine.

Dynamite No. 2 is a mixture of 18 parts nitroglycerine, 71 of potassium nitrate, 10 charcoal, and 1 of paraffin wax.

Lithofracteur contains 50 parts of nitroglycerine and 50 of a mixture of kieselguhr, wood meal, barium nitrate, and a little sulphur.

Carbonite contains 25 parts nitroglycerine and 75 of a mixture of wood meal, potassium and barium nitrates, and a little sodium carbonate.

There are many similar mixtures in use, especially in America. Generally speaking, the smaller the percentage of nitroglycerine the slower they are in action, and hence the greater the rending and lifting, and the less the shattering effect.

All the dynamites are disintegrated by water. They exude their nitroglycerine, which may become dangerous. All freeze at low temperatures, in which state they behave erratically, and are dangerous to handle. They require to be thawed before use, which should be done carefully in the proper apparatus, and not in the rough method of some miners (exposing

cartridges to the heat of a fire), which has led to many fatal accidents.

Blasting gelatine is another valuable explosive invented by Nobel. It consists of 5 to 7 parts of collodion cotton dissolved with the aid of heat in nitroglycerine, with the addition of a little sodium carbonate as preservative. It forms a stiff jelly, which does not exude nitroglycerine in contact with water, and is stored under water. It is made into cartridges like dynamite. It is much less sensitive than pure nitroglycerine, and comparatively safe to handle. It requires a strong detonator, as jellies do not transmit the detonating wave well, and is as powerful as pure nitroglycerine, the excess of oxygen in this substance supplying the deficiency in the collodion cotton. It is the most powerful explosive in use. Rate of detonation, 7,700 metres per second.

There are many mixtures in use containing blasting gelatine as their base, all milder in action, but very powerful.

Gelatine dynamite contains 80 per cent. of blasting gelatine, and 20 per cent. of a mixture of wood meal, potassium nitrate, and guncotton.

Gelignite contains 60 per cent. of blasting gelatine, and the remainder as with gelatine dynamite. It is a very powerful high explosive, with great rending and lifting effect, and much used as a blasting explosive in Britain.

There are numerous other explosives, with fancy names, very similar to the above.

Military uses of nitroglycerine explosives.—Nitroglycerine blasting explosives are not Service explosives, but all military engineers are expected to be familiar with their properties and uses. Large quantities are kept in mining districts, and in war time they are freely used in back areas. They are not suitable for use near the front line, as they are liable to be detonated by a moderate shock, such as the stroke of a bullet.

Cartridges of these explosives make excellent primers for the detonation of large charges of the safety explosive mixtures.

Military Smokeless Powders.

A gunpowder, to be smokeless, must contain no mineral matter which would produce solid products of combustion. This excludes all mineral nitrates, except ammonium nitrate, and attempts to use this as a substitute for saltpetre were defeated owing to its hygroscopic nature.

Before 1860, von Lenk, in Austria, had provided several field batteries with guncotton cartridges. In order to slow its rate of combustion, it was twisted into threads and compressed, but although it then burns slowly under atmospheric pressure, the high pressures in a gun finds out the pores. The flame gases penetrate, the explosion is then so violent that the gun is liable to be destroyed, as was soon found.

In 1875, Shultze powder appeared. It consists of nitrated grains of purified wood, impregnated with nitrates. It was still porous, but the density was so great that the rate of burning was slow enough to make it suitable for shot guns.

It was some time before it was realised that if the rate of combustion was to be under control, the porosity of the substance must be completely destroyed: that no amount of mechanical pressure will do this, and the only way is completely to dissolve it, or at least completely gelatinise it by means of a solvent. When the solvent is evaporated the substance will then be impervious to flame gases at the highest chamber pressures, and burn regularly from the surface only.

The first to realise and make practical use of this fact was Mr. Walter F. Reid, who, with D. Johnston, took out a patent in 1882 for E.C. smokeless powder. This consisted of grains of guncotton impregnated with nitrates, and treated with alcohol-ether. As the guncotton contains a fair amount of soluble nitrocellulose, this was gelatinised and formed an impervious coating and binding for the other portions. The result was a good, almost smokeless powder, which is in use to this day.

With the truly gelatinised explosive, the time of combustion of a charge can be regulated by the diameter of the cord or stick, and so adjusted to the various sizes of guns, or rather to the length of the gun, that the whole charge may be consumed just before the shell emerges from the muzzle. It is also necessary that the rate of production of gas should increase as the shell moves forward in the bore and the space enlarges, so as to maintain the pressure. This is partly brought about by the rate of burning of cordite increasing with the pressure. Take Manse and Petavel's equation, $V = a_0 + ap$, where a_0 is the rate of burning at no pressure, $a = \text{const}\cdot a_0 = \cdot 5$ cm. for cordite and $a = 0\cdot 018$. Therefore in a field gun, where the maximum pressure = 15 tons per sq. in. = 2,240 atmospheres, roughly, the cordite commences burning at the rate of

·5 cm. per second, and at 40 cms. per second at highest pressure.

But the rate of gas production depends also on the surface exposed over which combustion is taking place. With a cylindrical rod the surface diminishes as combustion proceeds. With a flat strip it is practically constant, and the surface is large. With a tube or perforated cylinder it increases as the interior burns away. Hence the various forms—cords, strips, tubes, and flakes, of which specimens are shown.

There are two varieties of smokeless military powders in use at present: (1) *Nitrocellulose powders*, which consist of 99·5 per cent. of gelatinised nitrocellulose, and ·5 per cent. of a preservative; and (2) *Nitroglycerine powders*, which are gelatinised mixtures of nitroglycerine and nitrocellulose, with a few per cent. of a stabiliser.

American nitrocellulose powder (N.C.T.) is typical of the first class. It is made from soluble nitrocellulose containing about 12·5 per cent. of nitrogen. The purified nitrocellulose pulp is freed from water by pumping alcohol through it. Ether is then added to gelatinise it, and ½ per cent. of di-phenylamine to act as stabiliser, and the whole incorporated for about three-quarters of an hour, then pressed until it is a block of stiff colloid. This is pressed by hydraulic pressure through a die arranged to leave one or more perforations, and is cut into short lengths as it issues. For field guns, the rods have one perforation; for larger sizes, they have seven perforations. For a gun such as the 60-pr., the rod is 14 mm. in length and 5 mm. diameter, and has seven perforations. Hence the name N.C.T. It is also made in square flakes.

The greater part of the solvent is afterwards dried out, but from 3 to 6 per cent. remains as a constituent, as without it the powder is too brittle, and the rods are liable to break up and give unduly high pressures.

N.C.T. is a good powder, and fairly stable. It is the weakest of the smokeless powders. Charges must be about 10 per cent. heavier than with cordite to give the same muzzle velocity; but as this is due to the lower temperature of the gases, there is less erosion, and the guns have a longer life. It gives more smoke than cordite, but a less muzzle flash, and there is less danger of a back flash. It is hygroscopic to some extent, and must be protected from atmospheric moisture, as absorption of moisture alters the shooting.

N.C.T. is now much used in our Service for guns and howitzers, the charges being adjusted to give the same muzzle velocity as Cordite M.D.

German nitrocellulose powders are very similar. The rifle powder is made in small flakes which are graphited.

French nitrocellulose powders are different. Poudre B is made from a mixture of guncotton and soluble nitrocellulose. The alcohol-ether used as solvent dissolves the soluble nitrocellulose, and this coats and encloses the insoluble part. It is usually made in strips. It has not so good a history as N.C.T. and cordite. The loss of the "Liberté" in 1911, and the "Jéna," in 1907, was undoubtedly due to spontaneous combustion of poudre B; but this was probably due to other causes than inherent instability.

Russian powders were very similar to American N.C.T., but are of no interest now since the Russians have forgotten their use.

Cordite.

Cordite Mk. I. was for a long time the sole British propellant. It was the result of a series of experiments carried out under the direction of the late Sir Frederick Abel and Sir James Dewar, and its manufacture was commenced in 1889. It was based on Nobel's discovery that when nitrocellulose and nitroglycerine were thoroughly incorporated and gelatinised the sensitiveness of both was diminished, and the resulting substance formed a safe and powerful smokeless powder. Nobel's powder was ballistite, which contained 50 per cent. of collodion cotton dissolved in 50 parts of nitroglycerine, with a small percentage of camphor added as stabiliser. The collodion cotton was objected to as being unstable, and the camphor as volatile. The composition decided on was nitroglycerine 57 parts, guncotton 38, and mineral jelly 5. Acetone was used as the solvent. The mineral jelly (vaseline) was added to modify the violence of the explosion and act as a lubricant for the bore. But later it was found that it was completely burnt up, and also that instead of being a pure paraffin, as supposed, it contained unsaturated hydrocarbons, and was an efficient stabiliser.

Cordite Mk. I. is a very powerful propellant, but owing to the high temperatures produced it is very erosive, and as the result of the South African War a modified cordite, "Cordite M.D.," was introduced. It has the composition—guncotton 65, nitroglycerine 30, mineral jelly 5. Its power is about 10 per cent. less than that of

Mk. I., but the guns last three times as long. Cordite M.D. is the standard British propellant, although others are used at present.

The following is a brief outline of the manufacture.

The guncotton, lightly pressed into cylindrical primers containing 50 per cent. of water, is dried in air at 40° C., until the water is reduced to ½ per cent. It is then weighed into rubber-lined bags and the charge of nitroglycerine poured on. The two are worked by hand into a paste which is quite insensitive compared with either of its constituents. The cordite paste is put into a kneading machine, acetone is added, and incorporated for about three hours. Then the vaseline is added and more acetone, and it undergoes a further incorporation, forming cordite dough. The dough is pressed hydraulically through dies, and issues as cords, strips or tubes. The diameter of the rods and thickness of the tube walls vary from half an inch to one-hundredth of an inch. The acetone is driven off by exposure to warm air, which requires from three to thirty days.

Cordite varies in colour from light yellow to dark brown, according to the vaseline. It is one of the best and most stable of smokeless powders, but like the others is decomposing from the day it is made, and requires care in store and frequent inspection. Different sizes are distinguished by numbers, which give the diameter in hundredths of an inch in the case of sticks, and the outer and inner diameters in the case of tubes. Thus: Cordite M.D. 3¾; Cordite M.D.T. 20–10. For strips the numbers give the width and thickness.

In store cordite should be kept cool and not exposed to the direct rays of the sun. In ships the magazines are artificially cooled. When cooled below about 6° C. the nitroglycerine freezes, and appears as an exudation on thawing. The cordite is said to "sweat." The nitroglycerine is reabsorbed on standing. Sweating cordite should be handled carefully, but may be fired in this condition. Water does not injure it, but it should be dried before use.

There are other modifications of cordite. One is similar to Cordite M.D., except that a mineral jelly containing a larger percentage of unsaturated hydrocarbons is used to increase the stability. In a new modified cordite soluble nitrocellulose is used instead of guncotton, and alcohol-ether is used for the gelatinisation instead of acetone. It contains a larger percentage of nitroglycerine than Cordite M.D., but is very similar, although not quite so powerful.

Ballistite is also used as a military powder. The original ballistite contained 50 parts nitroglycerine and 50 of collodion cotton gelatinised by heat, with the addition of ½ per cent. of diphenylamine as stabiliser. It is rolled into sheets and cut into small square flakes. It is the most powerful of all the smokeless powders, but the most erosive, and only suitable for howitzers where the chamber pressures are low. A modified ballistite has been introduced in which the more stable highly nitrated cellulose is used, and the percentage of nitroglycerine diminished. It has the same characteristics as the other, but is not quite so erosive. The flakes are sometimes graphited. Specimens are shown.

INDUSTRIES AFTER THE WAR.

IV.—Textiles (*continued from p. 717*).

Wool and Woollen Goods.

The British Empire controls nearly 70 per cent. of the exportable surplus of wool for clothing purposes, and between 80 and 90 per cent. of the finer description of this important raw material, viz., merino, large quantities of which, previous to the war, were used by enemy manufacturers as well as by our own mills. The table given on page 731, abridged from one prepared by the Board of Trade Committee, and included in their report, shows the extent of wool production in the year 1915.

In the United States of America, and in the majority of European countries, domestic clips are insufficient for home consumption, and are, or were, supplemented by supplies from the British Empire and the next largest exporter, South America. A serious decrease in the world's wool resources, particularly noticeable in the case of merino, has been experienced during the past few years, mainly owing to a succession of droughts in Australia having caused the number of sheep in the Commonwealth to fall from 93 million head in 1911 to 66 million in 1915; expansion of the frozen meat trade, accentuated by the war; and the breaking up of so much pastoral land in South America, the latter being due partly to the gradual settlement of the Argentine Republic, and partly to the strong demand for wheat in the past four years. Moreover, in Australia cross-breeds are in some degree supplementing merinos. The former mature more rapidly than merinos and are therefore of greater value for mutton. At the Antipodes a special factor is the rabbit pest. It is calculated that the damage these animals do by destroying "feed" is, on the basis of pre-war prices for wool, not less than £5,000,000 per annum. Virtually a British monopoly, upwards of 30 per cent. of merino wool found its way to Germany and Austria, which, without it, would have been unable to turn out, at any rate upon the same scale,

	Total Production.	Merino.	Cross-bred.	Carpet, Wool, etc.
	lbs.	lbs.	lbs.	lbs.
British Empire	1,144,000,000	676,000,000	408,000,000	60,000,000
Allies*	480,000,000	107,550,000	68,450,000	304,000,000
Neutrals	1,108,000,000	278,000,000	492,000,000	338,000,000
Enemy States	67,000,000	13,000,000	54,000,000	——
Total	2,799,000,000	1,074,550,000	1,022,450,000	702,000,000

* United States not included.

the kind of fabrics in which those countries excel. For their purposes South American merino is unsuitable.

After the war there will be an abnormal demand for wool, arising from various causes, *e.g.*, the provision of civilian clothing for the disbanded soldiers; the exceptional requirements of that portion of the non-military population who are buying fewer clothes than in peace times; the re-stocking of devastated districts in Allied countries; our pledges to them, etc. For these and other reasons it appears to the Committee that efficient control of the Imperial supplies will be necessary after the war. Of three measures suggested as a means of effecting this object—export duties, shipment under licence during the period of reconstruction, and State purchase—the Committee favours the second as offering the smallest difficulties. Under such a scheme, it is explained, exports to enemy countries would be prohibited for at least one year after the conclusion of peace or for any longer time considered desirable, and exports to neutral countries restricted to the quality of wool available after the wants of the British Empire and the Allies have been satisfied. If an Imperially co-ordinated policy of licensing "carried out under the direction of small committees of practical men" were to fail, then it appears to the Committee that the only alternative is State purchase. The Committee says that "too much stress cannot be laid upon the fact that this question is essentially one for joint consideration by the Governments of Australia, New Zealand and South Africa in consultation with H.M. Government, and can only be satisfactorily settled by a frank interchange of views and the adoption of a common policy. No effective action is possible without the full co-operation of all the Governments concerned."

As stated above, more than 30 per cent. of the Empire's merino clip in 1913 went to the enemy, but this does not show the full indebtedness of Germany to us. Part of the large exports of this article to France and Belgium was re-exported to Germany in the form of "tops." Of the Empire cross-bred wool Germany and Austria took 12 per cent.

In an exhaustive survey of our woollen and worsted trade, which among textiles is second to the great cotton industry, the Committee reminds us that, though scattered over the whole of the United Kingdom, its principal home is the West Riding of Yorkshire. Of worsted combing and spinning the Bradford district enjoys a practical monopoly, while about half the spindles and almost three-fifths of the looms are also engaged in the largest English county. Eleven years ago the trade produced goods worth about £70,000,000, and gave employment to upwards of 260,000 persons, male and female. In view of subsequent expansion it is estimated that in 1913 about 40 per cent. of the outturn, valued at nearly £38,000,000, was exported. Germany was the most considerable of the markets for semi-manufactured goods. In that year the value of the tops, noils and waste we sold to her was £2,065,922, and of woollen, worsted, mohair and alpaca yarns £4,798,410. Of the woollen piece-goods we exported, our Overseas possessions took 34 per cent., the European Allies 16 per cent., South America 15 per cent., the European enemies 14 per cent., the Far East 8 per cent., European neutrals 7 per cent., and the United States 5 per cent. We imported about ten and a half million pounds' worth of woollen yarns and tissues, 84 per cent. of the former and 71 per cent. coming from Allied countries. Of cloth for men's use and heavier fabrics for women's wear not much reaches us from abroad. Our imports from Germany were mainly yarns, dress stuffs, velvets, and plushes. A large percentage of these goods was made in Alsace and the remainder in Saxony, in both cases apparently from material largely contributed directly or indirectly by the British Empire.

With reference to the outlets for the productions of British top-makers and spinners, attention is drawn to the possibility of expanding specified manufactures at home, and to the extension of business in the markets of the Allies. Temporary dislocation may be caused to certain combing and spinning sections, and the principal aim, the Committee says, should be to replace the German market with home-made goods of a type formerly manufactured in Germany from British tops and yarns. In common with other textile trades, the woollen industry has been handicapped since the war by the scarcity of dye-wares, bleaching powder, sulphuric acid, etc. The majority of the witnesses were in favour of the "immediate adoption of steps which may be considered necessary for the establishment of such subsidiary industries as are essential to the welfare of the main industry, so that we may be independent of foreign and, more particularly, of enemy sources of supply."

The Committee notes that the facilities afforded by the banks appear to be, as a rule, sufficient for

ordinary needs, but recognises that a change in the system of financing some branches of the export trade is necessary to meet and counteract German methods.

It is urged that any duties imposed should be upon a minimum scale in the case of Allied countries, and that every effort should be made to secure mutual tariff concessions, "the general view being that Russia in particular offers favourable opportunities for a considerable extension of British trade if modifications of her tariff in our favour could be brought about."

This section of the report concludes with an interesting account of a highly-specialised branch of the woollen trade, carpet-making, which is in the hands of a comparatively small number of firms having works in Kidderminster, the West Riding and in the West of Scotland, and employing, just before the outbreak of war, some 20,000 hands. One feature of the carpet industry is the tendency to eliminate the middleman as much as possible, in a large number of cases the manufacturer dealing direct with the retailer. It is mentioned that the taste in carpets has changed entirely within the past few years, the present demand being for the seamless woven square rather than for the made-up carpet. This has necessitated the installation of new and more costly machinery.

One point referred to has a bearing on the scheme for the Promotion of Industrial Art to be considered at a meeting of the Royal Society of Arts on Monday, October 28th. The Committee says: "Before the war some difficulty was experienced in securing sufficient designers with original ideas. It is obvious that a great deal of the success in the carpet industry depends on the originality and attractiveness of the designs produced. Before the war, a larger proportion of the designs were of British origin, although a few were purchased in France. To remedy the tendency towards stereotyped designs, it was suggested that more attention should be paid in the technical and art schools to the teaching of design, especially in those centres in which carpets are produced, *e.g.* Halifax, Glasgow, and Kidderminster."

The annual value of the trade is four and a half millions, and approximately a third of the productions are exported, the largest market being British possessions. The value of the carpets and rugs we imported in 1913 was only about £700,000, and the bulk were re-exported. The principal sources of supply were India (£151,606), Turkey (£214,378), and Belgium (£88,900). The carpet industry thinks that there should be a minimum tariff of 20 per cent. *ad valorem* upon goods from Allied countries; a maximum tariff of 30 per cent. *ad valorem* upon goods from neutral countries; and a surtax of 50 per cent. upon all carpets from enemy countries. The Committee simply records these opinions.

(*To be continued.*)

OBITUARY.

Edward Scripps Tudor.—The Society has lost its oldest Fellow by the death of Mr. Edward Scripps Tudor, which took place on September 7th, in his eighty-eighth year. He was elected in 1852, and had thus been a member for sixty-six years.

Mr. Tudor was a well-known merchant in the City, and at one time he was Master of the Haberdashers Company. In addition to his business activities he was deeply interested in charitable and educational work. He founded the hospital at Orford Road, Walthamstow, which, starting as a Cottage Home for Children in 1878, subsequently developed into the present building with fifty beds. He was also a generous supporter of numerous other hospitals, convalescent homes, and charities; and he acted for many years as a trustee of the Forest School for Boys.

GENERAL NOTES.

Paper Driving-belts.—Some particulars of the paper substitute driving-belts, which are now being introduced into German workshops, are given in the *Bulletin des Usines de Guerre*. The paper is cut into narrow bands which are then spun. The belts are made by weaving or braiding. Woven paper belts are of two kinds—paper fabric and paper thread belts, the former being the more frequently used. The fabric is first cut into bands 40 m. long, which are subsequently made up according to the desired width and thickness. A core of strengthening material is interposed, either cotton or sheet metal, though more recently these cores have consisted of paper thread and metal wires interwoven. The core is surrounded with the paper strips and the whole sewn with strong thread. Belts so prepared are said to be very flexible and to wear satisfactorily. Woven paper belts have a tensile strength of from 100 to 125 kilos per centimetre of width.

Adulteration of Saccharine.—According to the *Münchner Neueste Nachrichten*, private trade in saccharine and dulcine is forbidden in Germany by the Saccharine Law of 1902. Recently the surreptitious traffic in these articles has assumed considerable dimensions, and advantage has been taken of this fact to practise fraud. Preparations are frequently offered as saccharine which are not saccharine at all, but consist of carbonate of soda, gypsum, cement, etc., or are adulterated with such ingredients. This pretended saccharine is sold at many times the official price, and generally in original packages which have already been used, or fraudulent imitations of the official packages, or forged Swiss packages. The purchaser runs the risk of suffering considerable injury to health.

CANTOR LECTURES.

MILITARY EXPLOSIVES OF TO-DAY.

By J. Young, O.B.E., A.R.C.S., F.C.S.,
Chief Instructor in Science, Royal Military Academy, Woolwich.

Lecture III.—Delivered April 22nd, 1918.

High Explosives for Shell Filling.

A high explosive, in order to be suitable for shell filling, must possess special qualities not necessary when it is used for other purposes, even in bombs and torpedoes. *Firstly*, it must have great power, that is give much gas and heat. *Secondly*, it must be insensitive enough to stand the great shock of firing, and even the impact on an armour plate without detonating, so that it may penetrate the latter before the fuse acts. *Thirdly*, it should have a high density, so that a large weight may be enclosed in the limited space, and a high velocity of detonation, so that it may have a great shattering effect. *Finally*, it must detonate completely and with certainty when required, by the action of a detonator which is itself not too sensitive to stand the shock of firing.

These provisos exclude all the nitroglycerine and chlorate explosives, which are too sensitive. Also the ammonium nitrate class, such as ammonal, which are too insensitive, and require a fulminate detonator. Large fulminate detonators in a shell are unsafe, and may lead to premature detonation, although they have been used. The problem of detonating a shell safely and with certainty is the most difficult of all, although it has been solved fairly satisfactorily now. When a shell merely explodes (*i.e.* the filling burns) the action is so slow that the shell breaks up, a large amount of the filling is blown away unburnt, and very feeble effects are produced. Many of the lyddite shells used in the South African War behaved in this way, and except for emitting poisonous vapours did little harm to the enemy.

None of the shell high explosives possess all the desirable qualities. Those now in use have little more than half the shattering power of blasting gelatine. All are products derived from the distillation of coal.

Formerly gunpowder was the only explosive used in shells. Sprengel pointed out in 1871 that picric acid could be detonated, but no attempt was made to use it. A new epoch in shell filling was commenced in 1885 when M. Turpin showed that picric acid, if brought into a dense and homogeneous state, made a safe filling for shells, and could be detonated with tremendous shattering effect. It was adopted by the French under the name of Melinite; later by the British under the name of Lyddite. Other nations also adopted it under various fancy names. Still later tri-nitro-cresol, tri-nitro-toluene, and other aromatic nitrocompounds of a similar nature were introduced, and are now used.

As previously stated, the basic substances required for the manufacture of these explosives are obtained from coal. When coal is distilled in the manufacture of coal gas, about 16 to 20 gallons of tar are obtained from each ton. The tar is a complex mixture, and contains only about ½ lb. of benzene, toluene, and xylene, required by the explosive manufacturer. The coal gas contains about 1 per cent. by volume of the vapours of these substances, equal to about 19 lb. per ton of coal. Formerly this was allowed to remain in the gas, and was the cause of the greater part of its luminosity when burnt in a flat burner. But on the advent of war, and the urgent demand for these hydrocarbons, it was necessary to "strip" the gas, or rob it of these constituents, a process already in use in connection with the gas from coke ovens. The result is that the normal luminosity of coal gas has decreased, but this has not much effect on its heating power and use in

incandescent burners, while 13 to 20 lb. of these mixed hydrocarbons in the form called benzol are now extracted from each ton of coal.

A writer in the *Times* Engineering Supplement states that 40 millions of gallons of benzol can be obtained from the gasworks of Great Britain, in addition to 60 millions already obtained from the coke ovens.

When coal tar is distilled the first portion which comes over at temperatures up to 150° C. is called the "light oil," and is crude benzol, mostly benzene and toluene.

In order to extract the hydrocarbons from coal gas it is submitted to a washing action by a solvent. At first coal tar was used, but the best solvent, and that now generally used, is the "green oil," itself a special high-boiling distillate from the tar. The oil absorbs the benzol, and is afterwards heated and allowed to flow down over a series of superposed cast-iron trays, up through which a jet of steam is passed. The steam vaporises the hydrocarbons, which are carried away and condensed. The oil is returned to the scrubbing plant and can be used over and over again.

The composition of the benzol varies with the quality of the coal used and the process of stripping. It contains 50 to 70 per cent. of benzene, 10 to 40 per cent. of toluene, 1 to 3 per cent. of xylene, and smaller amounts of naphthalene and acids. These substances are afterwards separated by fractional distillation. At present there is a great demand for toluene, but the benzene is also used as a nitro compound in explosives, and in a synthetic process for making phenol.

The next fraction from coal tar distillation—the "middle oil"—contains phenol and other bodies, and the later fractions—the "heavy oils"—also contain valuable compounds.

Phenol (C_6H_5OH), commonly called Carbolic Acid, is obtained from the middle oil of tar distillation. The oil is treated with caustic soda, which dissolves the phenol, cresol, and similar bodies. The solution is removed and treated with sulphuric acid, which precipitates the phenol, etc. The phenol is then separated by distillation. Pure phenol forms a mass of crystals somewhat like sugar in appearance and very different from the crude black liquid called carbolic acid used as a disinfectant. Pure phenol melts at 44° C. and boils at 182° C.

Picric Acid ($C_6H_2(NO_2)_3OH$).—When phenol is added to conc. nitric acid a violent reaction takes place, and the tri-nitro compound is formed—

$$\underset{\text{Phenol}}{C_6H_5(OH)} + \underset{\text{Nitric acid}}{3HNO_3} = \underset{\text{Picric acid}}{C_6H_2(NO_2)_3OH} + 3H_2O.$$

Other reactions take place simultaneously, and resinous compounds are formed. In practice the manufacture takes place in two distinct stages. The methods and proportions of acid used vary considerably. The following method works well:—

First the phenol is mixed with its own weight of conc. sulphuric acid, and heated to over 100° C. for some time. It combines with the acid to form phenol sulphonate ($C_6H_4OHHSO_3$).

The sulphonate is mixed with water and added, a little at a time, to conc. nitric acid. The mixture is kept cool at first, and a di-nitro is formed. Afterwards it is heated by steam for several hours until all oily matters have disappeared, and a clear yellow liquid is formed. This liquid is next allowed to cool, and crystals of picric acid are deposited. The crystals are thoroughly washed with water until free from acid, and wrung as dry as possible in a centrifugal machine. They are afterwards spread on glass tables and dried in air at about 50° C.

Picric acid forms yellow needle-shaped crystals, melting at 122·5° C. when pure. Any impurity lowers the melting-point, so this is the best test for purity. It is slightly soluble in cold water, has an intensely bitter taste, and is poisonous. Its chief use formerly was as a dye for silk and wool.

When heated to about 300° C. it inflames, and burns with a hot flame, and clouds of black smoke containing free carbon. A large mass thus inflamed will burn for a while, but owing to the heat given out will probably end by detonating. A small quantity thrown on a red-hot plate flashes off; when the plate is white-hot it may detonate. It is not very sensitive, and will only just detonate when hammered on an anvil. Half a gram of mercury fulminate will set up the detonating wave, one to two grams will detonate any quantity with certainty, even in its densest form. It can also be detonated by picrates and some other compounds less sensitive than fulminate, and these are used in shells.

Use in shells.—The picric acid is melted in baths heated by oil or hot air and poured into the shell, which is cleaned inside and lined with a non-metallic varnish. A former is placed inside and removed when the acid sets, so as to leave a central cylindrical cavity for the exploder. In this cast form it has a

density of 1·62, and is called Lyddite. It is the most powerful and shattering explosive used in shells. When fully detonated it gives a cloud of black smoke, owing to its deficiency in oxygen, and this is useful for observation purposes, and also for indicating to the gunner that his shells are detonating and producing the desired effect. When the detonator fails, and the shell merely explodes, the action is slow, and much picric acid vapour is blown out, so that the smoke is yellow. The effects are very feeble, although the vapours are poisonous.

The rate of detonation is about 7,700 metres per second.

In spite of its great merits, picric acid has now been largely replaced as a shell filling by tri-nitro-toluene and Amatol, for the following reasons.

Defects of picric acid. — First, the high melting-point prevents the use of low pressure steam as a heating agent, and involves methods which constitute a certain danger. Second, picric acid is a true acid, and when in contact with metals, or metallic compounds such as rust, lime, plaster, lead-paint, etc., forms picrates. All picrates are much more sensitive than the free acid to simple shock; the heavier the metal the more sensitive the picrate, and lead picrate is very sensitive and powerful. If a small amount of one of these was in the shell it might be detonated by the shock of firing, and the detonation would extend to the filling, causing a premature explosion, and the destruction of the gun and detachment.

This may be illustrated by mixing some picric acid with an equal bulk of lead peroxide or red lead, and heating on a tin plate as much as would lie on a sixpence. The mixture detonates with a force only less than that of nitroglycerine and blows a hole in the plate. The mixture also detonates violently by moderate percussion on an anvil.

Hence all operations connected with the preparation of picric acid, the shell filling, and inspection of shells, must be conducted in rooms free from lime or plaster. The shells must be clean and lined with non-metallic varnish. No lead paint is used even on the outside, and no lead alloys in the fuse or anything which would come into contact with the filling.

Given that the picric acid is pure, and proper precautions have been taken, it is quite safe, and the most powerful shell filling in use. It is also unaffected by high atmospheric temperatures, unlike T.N.T., and is specially suitable for tropical climates. The problem of detonating a lyddite shell safely and with certainty is now solved, although this was not the case during the Boer War, or even in the early days of the present war.

Picrates.—When a hot saturated solution of picric acid is mixed with a solution of a metallic salt a picrate is formed, and is easily crystallised out. With potassium carbonate, potassium picrate ($C_6H_2(NO_2)_3OK$) is formed. This, mixed with potassium nitrate, has been used for charging torpedo warheads. With ammonia ammonium picrate is formed ($C_6H_2(NO_2)_3ONH_4$). 43 parts ammonium picrate and 57 parts potassium nitrate form picric powder. It is used as a detonator for lyddite shells.

Tri-nitro-cresol.—Cresol ($C_6H_4OHCH_3$) is a very similar compound to phenol, and also obtained from coal tar. When nitrated in the same way it forms a tri-nitro-cresol ($C_6H(NO_2)_3OHCH_3$). Its properties are very similar to those of picric acid, and it has been used as a shell filling. In Austria it is called Ecrasite; in France, Cresylite. In France it is mixed with picric acid in order to produce a melinite of a lower melting-point.

Tri-nitro-toluene ($C_6H_2(NO_2)_3CH_3$).—Usually called T.N.T., this substance, at present the most important of the shell high explosives, is known in the Service as Trotyl, and is used in other countries under various fancy names, such as Tolite (France), Trilite (Spain), Tritolo (Italy), etc.

It is made by nitrating the hydrocarbon toluene, obtained from the distillation of coal, as previously described. The toluene for this purpose must be pure, clear, and water white. Boiling-point, 110° C. When treated with a mixture of conc. nitric and sulphuric acids it is converted successively into the mono-, di-, and tri-nitro compounds. The following equations represent the successive steps:—

(1) $C_6H_5CH_3 + HNO_3 = C_6H_4NO_2CH_3 + H_2O.$

(2) $C_6H_4NO_2CH_3 + HNO_3 = C_6H_3(NO_2)_2CH_3 + H_2O.$

(3) $C_6H_3(NO_2)_2CH_3 + HNO_3 = C_6H_2(NO_2)_3CH_3 + H_2O.$

The sulphuric acid combines with the water liberated in the reactions.

The complete conversion into the tri-nitro is a long and difficult process, and different methods are used in different works. In some it is done in one operation by the long continued digestion with the mixed acids. In others there are two stages: first a conversion into the

di-nitro, and then by a treatment with fresh acids a conversion into tri-nitro. In others the conversion is done in three stages.

In one method 1 part of toluene is run into 1·7 parts by weight of mixed acids containing 3 parts of sulphuric to 2 parts of nitric. The pan is steam-jacketted, and the result of the reaction is mono-nitro-toluene.

When the reaction is over the acid is run off, and a fresh acid mixture run in and the pan heated. The di-nitro compound is the result of this reaction. The di-nitro-toluene, which is a liquid at this temperature, is run off and allowed to solidify.

The di-nitro is next heated with conc. sulphuric acid until it dissolves, and then run into a pan containing one and a half times its weight of conc. nitric acid, the mixture being kept cool by coils of lead pipe in which cold water is circulated. The mixture is next heated to about 100° C. for several hours, until gas is no longer evolved, being kept well stirred. This action converts most of it into the tri-nitro.

The conversion by a continuous process in one operation has been greatly improved recently, and is now much used.

The acids are then run off, and the still liquid substance well washed with hot water and dilute soda. When it cools it is crude, impure tri-nitro-toluene, and melts at about 70° C.

Purification—The crude T.N.T. made in this way contains impurities, mostly lower nitro-compounds, and isomers of the true T.N.T. The chief of these are oils at the ordinary temperature, and their presence is indicated by a lowering of the melting-point. Pure T.N.T. melts at 81·5° C., but the final purification is so difficult that a product which melts at 80° C. is called "pure."

The chief objection to the presence of these oily impurities is that if the T.N.T. is used as a shell filling, either alone or in one of the higher grades of amatol, the oils have a tendency to separate, and this tendency is increased by a rise in temperature, or pressure in the shell caused by evolution of gas, which sometimes occurs. The oils penetrate porous substances sometimes used to contain the exploders, and creep past the threads of screws. When they enter the gaine exploder and wet the contents, these become insensitive. If the shell is fired in this condition it will fail to detonate, and is a "dud." A new exploder, however, will remedy matters.

Various methods of purification are used. Treatment of the finely-divided substance with hot water in a centrifugal machine has given good results. Washing with cold alcohol is also used, as the impurities are more soluble than the pure T.N.T. For the highest grade of purity the substance is dissolved in hot alcohol and allowed to crystallise out.

Properties. — Pure T.N.T. forms yellow crystals melting at 81·5° C. They are insoluble in water. When heated to about 300° C., T.N.T. ignites and burns with a hot, but very smoky flame. When a large mass is involved the heat given out will invariably raise the temperature to the detonating point. The disasters in East London and at Halifax are examples of this. When fires of this extent are once properly going, it is hopeless to attempt to extinguish them. The most sensible thing to do is to clear the premises and let matters take their inevitable course. T.N.T. is more insensitive than picric acid, and very difficult to detonate by hammering. It is fully detonated by fulminate, except when in the form of cast slabs untamped, when the addition of a little lead azide to the fulminate is necessary. Fulminate detonators are used in bombs, torpedoes, and grenades. T.N.T. can also be detonated by less sensitive substances, such as picric powder and tetryl, and these are used in shells. Its density when melted and cast is 1·55 – 1·6.

T.N.T. is even more deficient in oxygen than picric acid. When fully detonated, the gases liberated consist of CO, H_2, and N_2, and the free carbon liberated forms a thick column of black smoke: hence the name "coal boxes" and "Jack Johnsons." The velocity of detonation in its densest form is about 7,000 metres per second. The power is less than that of picric acid, about in the proportion of 91 : 100. Owing to the inferior velocity of detonation, the shattering effect (brisance) is proportionately still less, about 87 : 100.

Advantages of T.N.T.—The special qualities of T.N.T., which have caused it largely to replace picric acid as an explosive, are as follows:—

(1) Its lower melting-point renders it much safer during the melting and manipulations required in shell filling. (2) It is a neutral substance, and does not form sensitive compounds with metals and their oxides, like picric acid, so no particular care is necessary in cleaning and lining the shells, lead-free paint, etc. Alkalies, however, diminish its stability and render it sensitive, so the shells must not be cleaned with caustic soda. (3) It can be mixed safely with oxidising agents, which is not the case with picric acid. As little as

10 per cent. of T.N.T. mixed with ammonium nitrate gives an explosive as powerful as the pure substance itself. The amatols thus made more than double our resources as regards high explosives.

Only the highest grade of purity is used, as crystals and pellets, in the exploders for high explosive shells. A slightly lower grade is used for filling shells and for making shell amatol. The more impure substance, with a melting-point five or six degrees below normal, is used for making amatols with a high percentage of ammonium nitrate, from which the oils are less likely to separate. This is suitable for mining, bombs, grenades, etc. For shells to be used in the tropics only the purest T.N.T. is suitable.

In shell filling the T.N.T. is melted in steam-heated pans and poured into the shell, where it sets into a yellow crystalline mass. A central cavity is left for the exploder. The detonating arrangements are mentioned later.

Amatol.—Amatol was dealt with in the first lecture. That with the higher proportions of ammonium nitrate, such as 80/20, is more difficult to detonate than when the proportion is lower, and is used in cases where fulminate detonators are used. The mixture most used in shells is 40/60. The mixing and introduction into the shell is done in various ways. Sometimes the T.N.T. is melted and the powdered nitrate stirred in. The plastic, semi-liquid mixture is poured into the shell. Sometimes it is milled cold, the powder introduced into the receptacle and stemmed (compressed), or it is compressed into slabs, which are then packed in. The same exploder is used as with pure T.N.T.

When an amatol shell detonates there is only a little grey smoke, and no definite indication as to whether detonation has been complete or not. For observation purposes a packet of smoke producer is put in. The power is a little greater than that of pure T.N.T., but the velocity of detonation much less—4,000 to 4,500 metres per second, so that the local shattering effect is much less. For some purposes this is even an advantage.

Amatol is the most used of all the shell high explosives at present.

Tetra-nitro-methyl-aniline ($C_6H_2(NO_2)_3NCH_3NO_2$).—This substance is known in the trade as Tetryl, and in the Service as C.E. (composition exploding). It is made by nitrating methyl or di-methyl aniline, substances used on the large scale in the manufacture of aniline dyes. The substance is dissolved in ten times its weight of conc. sulphuric acid, and the solution added slowly to 4½ parts of nitric acid of specific gravity 1·48. The temperature is kept between 44° and 55° C. On cooling, crystals of the substance are deposited, and are washed with water. It is completely purified by crystallising it from its solution in acetone, but inferior grades of purity from nitric acid and boiling water are in use for some purposes.

Properties.—It forms crystals of a fine yellow colour, melting at 129°–130° C. It is more sensitive than picric acid, and can be detonated readily by hammering. When ignited it burns with a very hot smokeless flame, and flashes off when thrown on a red-hot plate. It is readily detonated by a very small charge of fulminate, such as that used in shell detonator caps, is very powerful, and has a velocity of detonation of over 7,000 metres per second. It is an excellent initiator of detonation in other less sensitive explosives.

Uses of Tetryl.—As tetryl (or C.E.) is an excellent initiator of detonation, and has a sensitiveness intermediate between that of fulminate and ordinary shell fillings, it is much used as an intermediary. It is used in the form of powder, grains, and compressed pellets or cylinders up to a few ounces in weight. It is sometimes added to fulminate in ordinary detonators. Compressed cylinders are used in the magazines of some fuses. In powder, pellets, and cylinders it is used in the gaines or detonators for T.N.T. and amatol shells, with which it is very effective.

The Germans also use a compressed cylinder of C.E. as the high explosive charge for some gas shells. The uses of C.E. are extending, although it will probably prove too sensitive, as well as too expensive, for use as a complete shell filling.

Tetra-nitro-aniline ($C_6H(NO_2)_4NH_2$).—This substance is made by the nitration of ordinary aniline. It has great possibilities, although not adopted as a Service explosive. It is a yellowish powder, which cannot be melted without decomposition. When ignited it flashes off without smoke. Its sensitiveness to blows is about the same as that of C.E. It is easily detonated by fulminate, and is said to be as powerful as pure nitroglycerine, if not more so.

It is probably too sensitive to be safe for use as a shell filling, although there seems no reason why it should not be used for other purposes. It is said to have been used in

shells during the present war, but not in our Service.

Hexa-nitro-diphenylamine ($C_6H_2(NO_2)_3)_2NH$).—This is made by nitrating diphenylamine. It is a yellow powder, which does not melt. It is a powerful high explosive, but rather too sensitive for a shell filling. A mixture of this with T.N.T. has been used by the Germans in aerial bombs. They also use it as a high explosive charge in some gas (chemical) grenades.

Tri-nitro-anisol ($C_6H_2(NO_2)_3OCH_3$).—This substance is made by the nitration of anisol, a liquid. Chemically it resembles picric acid. It has been used in shells and bombs.

Nitro-benzenes.—Benzene also gives a series of high explosives. Di-nitro-benzene, readily formed by the action of mixed nitric and sulphuric acids on benzene, is a yellowish solid. It is too deficient in oxygen to be a good explosive in itself, but when mixed with oxidising agents is a powerful explosive. Thus, Bellite and Roburite are mixtures of di-nitro-benzene and ammonium nitrate, the latter having a little nitro-naphthaline added as well. Bellite is used in grenades.

Tri-nitro-benzene ($C_6H_3(NO_2)_3$).—This is also made by the nitration of benzene with mixed nitric and sulphuric acids, but the process is a long one, and full nitration difficult, which has prevented its being used to any great extent. It resembles T.N.T., but is a more powerful explosive.

Methods of Detonation.

Initiators of detonation.—Detonation can be set up in a high explosive charge by simple shock, and this is used in the case of percussion caps, but with large charges a combined shock and intense heat, supplied by some sensitive substance, is most effective in initiating detonation. The nature of the shock is important, and what is best for one high explosive is not necessarily best for another, but in all cases it must be very sharp and sudden, so as to produce momentary intense pressure. Fulminate of mercury is the most generally useful and effective substance for initiating detonation. It is also used in percussion caps for igniting powder charges.

Fulminate of mercury ($C_2N_2O_2H_g$).—It is made by dissolving mercury in nitric acid and acting on the solution with alcohol. Various formulæ are used for its preparation. In one used by Chandelon, which gives good results, one part by weight of mercury is dissolved in ten parts of nitric acid of specific gravity 1·4. When the solution is at 54·5° C. it is poured into ten parts of alcohol of specific gravity ·83. As much as 7 lb. of mercury can be used at one operation. The preparation should be done in the open air, and involves a certain amount of danger.

For preparation on the small scale for experimental purposes, the following I have never known to fail: Dissolve 8 grams of mercury in 70 c.c. of conc. nitric acid of specific gravity 1·45 with the aid of gentle heat. When completely dissolved, and the temperature is not above 40° C., pour into it 90 c.c. of alcohol of specific gravity ·87. All flames near should be extinguished. Next heat the beaker containing the mixture in a hot water bath, until bubbles begin to form and a reaction begins. The reaction is violent, and dense white fumes containing various nitro compounds are given off. When the reaction is nearly over, fill the beaker with water. The fulminate will fall to the bottom. It should be filtered off and washed free from acid. It can be dried quickly by first washing with alcohol until free from water, and then with ether. In a few minutes it will be ready for use.

Fulminate is a crystalline powder, white when pure, but usually grey owing to some free mercury. It is the most sensitive explosive employed practically, detonates easily between iron surfaces, can be detonated between lead and iron, but not between surfaces of wood. It is quite safe to keep when wet. It is usually dried by exposure to warm air (104° F.), and when dry, owing to its sensitiveness, kept in packets of 120 grains as a maximum. When pure it will stand a high pressure, but with the least admixture of grit of any kind a slight pressure will explode it. It is insoluble in cold water, and only slightly so in hot, one part in 130 of water.

When ignited in the open, it burns with a very sudden flash and slight report. But when even slightly enclosed, as in a thin copper tube, and ignited, the first few grains which burn produce sufficient pressure to detonate the remainder. It is this property which makes it of such efficacy in detonating other explosives. Its density is 4·4, and when highly compressed its detonation gives, probably, a higher instantaneous pressure than any other substance in use, except, perhaps, the azides.

Whether exploded or detonated, the products are carbon monoxide, nitrogen, and mercury ($C_2N_2O_2H_g = 2CO + N_2 + H_g + 114{,}000$ cals). If

some fulminate be sprinkled on a clean glass plate and ignited, the mercury is deposited on the plate and forms a mirror, which makes a pretty experiment.

The flash from fulminate is too sudden to ignite gunpowder, which is simply blown away. When required in percussion caps for the ignition of cartridges, it is mixed with potassium chlorate and antimony sulphide. This composition acts more slowly and gives a long, hot flame. Sometimes ground glass is added to increase the sensitiveness to percussion.

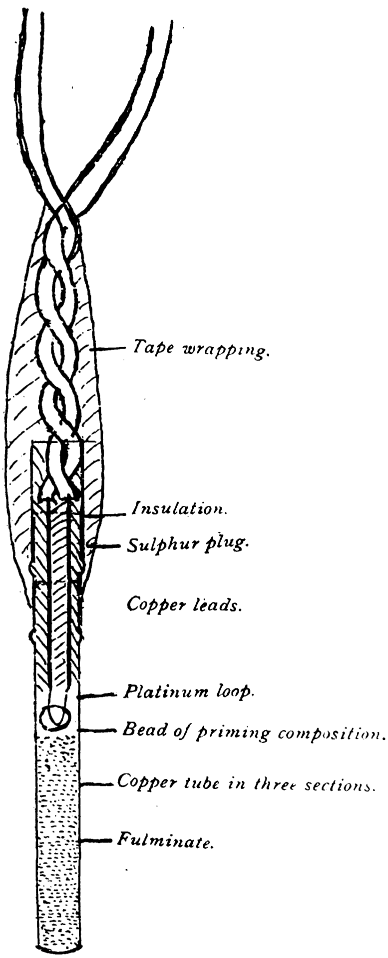

FIG. 4.—ELECTRIC DETONATOR.

The azides, derived from hydrazoic acid (N_3H), are even more effective initiators of detonation than fulminate. Where ·25 gram of fulminate is the minimum which will detonate T.N.T., ·05 gram of lead azide will suffice, and where mercury fulminate alone fails with cast slabs of T.N.T. untamped, an addition of lead azide succeeds perfectly. Lead azide (N_6Pb) is used to some extent at present, either alone or in combination with fulminate. Fulminate, however, is the standard.

The uses of tetryl, picric powder, and some others as initiators of detonation, will be referred to later.

Detonators.—Two varieties are in use, electric and non-electric. Non-electric detonators are thin solid-drawn copper tubes, containing a charge of fulminate. The fulminate is compressed by about 60 kilos on each, which gives it a density of about 2·2. The upper half of the tube is left empty for the insertion of the fuse, safety or instantaneous as the case may be, and is closed by a paper cap until required for use. The detonators are made in various sizes numbered from one to ten, and the numbers are common to all countries. No. 8, most used for military operations, is 55 mm. in length and 6 mm. diameter, and contains two grams of fulminate. No. 5, used for some hand grenades, is 30 mm. long and 6 mm. in diameter, and contains ·8 gram.

Electric detonators are constructed so that they can be fired from a distance by aid of an electric current. The construction varies, but the diagram (Fig. 4) shows the principle.

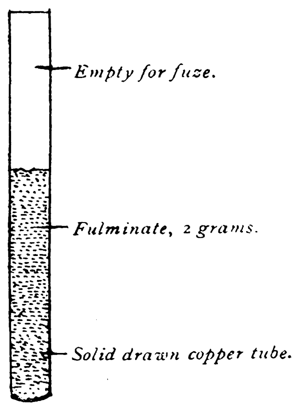

FIG. 5.—NON-ELECTRIC DETONATOR.

The lower part of the tube (which may be solid drawn, or have the end merely sealed with a plug of shellac) contains the fulminate. Copper leads are inserted into the upper end, and these are bridged over by a fine wire of platinum or platinum-iridium alloy. The bridge is wrapped round with fluffy dry guncotton, or imbedded in a bead of priming composition, and the leads are sealed in position with sulphur or other insulator.

When an electric current is passed through it the bridge fuses, ignites the guncotton, and this fires the fulminate. That most used in our land Service has a bridge, quarter-inch long, which requires ·8 ampere to fuse it, and contains forty-three grains of fulminate. The advantages of the electric detonator are many. It can be connected by cables to a point from which it can be fired with perfect safety. When once connected up it can be tested by a small current, and if necessary be left for months, yet be fired at a moment's notice. Also, a number of detonators in charges can be connected to a single firing-point and fired simultaneously. Great use is made of this where a number of land mines have to be fired in one operation. The current is usually supplied by the hand dynamo exploder, where not more than, say, fifteen detonators have to be fired at once. For larger numbers a dynamo, or battery of accumulators is used for certainty.

For hasty demolitions under stress of an enemy advance the ordinary detonator and fuze are used.

Detonation of charges of high explosives.—When the charge to be detonated is not liable to be submitted to any sudden shock, which is the case with land mines, aeroplane and trench mortar bombs, grenades, and even torpedoes—in fact all except shells to be fired from a gun—the problem is simple. The charge is built up in position, the cartridges being packed in their original cases in land mines. In the case of grenades, bombs, etc., a detonator is inserted and a piece of safety fuse inserted in the detonator. With torpedoes a specially large detonator to be fired by percussion is used. Aeroplane bombs are also fired by percussion. For land mines with large charges amounting to tons it is advisable to use several detonators distributed throughout the mass, if this is of one of the slower acting ammonium nitrate explosives, and even primers of blasting gelatine or dynamite may assist. The charge is properly tamped, openings being left for the insertion of the detonators. When fulminate detonators are used in this way failures are very rare.

Detonation of high-explosive shells.—The problem of the detonation of a high-explosive shell is much more difficult. The shell is subjected to an enormous shock in the act of firing, the detonating charge must be in intimate contact with the filling, and if fulminate were used there would be a great risk of this being detonated by the shock. This would detonate the shell in the gun, the gun would be destroyed, and probably the detachment.

On the other hand, when a less sensitive detonating charge is used, which at present means a less efficient one, there is a risk of failure. The shell may merely explode, with very feeble effect. This was frequently the case during the Boer War. The problem seems to have been solved by the introduction of the gaine method.

The Gaine.—The gaine is a metal tube screwed to the fuze which enters a cavity in the filling and makes good contact with it. This is very necessary. It contains a chain of substances, about four, of decreasing order of

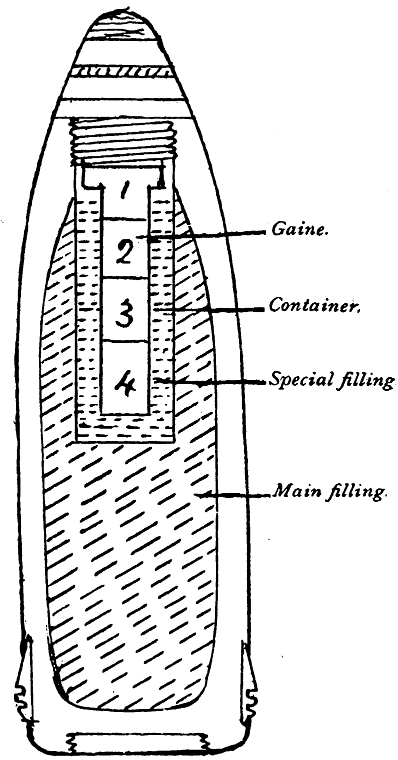

Fig. 6.—High Explosive Shell with Gaine.

sensitiveness starting from the fuse, and increasing order of violence of explosion. Use is made of the fact that a substance in powder is more easily detonated than when in compressed pellets, and pellets than a cast, dense solid. The actual substances vary with the shell and nature of the filling, but always start with gunpowder, which is very certain in action. Thus we may suppose the chain to consist of (1) gunpowder, (2) tetryl powder, (3) tetryl pellets, (4) T.N.T. pellets.

The action is started by a fulminate cap in the fuse, which fires the gunpowder. This

partially explodes and partially detonates No 2, which detonates No. 3, which in turn detonates No. 4, and this detonates the main filling. With fuse and gaine in good condition there are very few failures now.

The detonation of large shells is a simpler matter, as the walls are thicker and provide more efficient tamping. These are still often detonated by a single exploder charge of picric powder (for lyddite) in a recess in the filling.

Figure 6 shows diagrammatically the arrangement of a shell with a gaine detonator. No details of construction are given.

Tests for Explosives.

A large number of tests are applied to explosives for commercial use. Only an outline of those most important from the military standpoint can be given here.

(1) *Sensitiveness to shocks.* — This is important with regard to explosives which have to be handled within reach of enemy bullets. It is usually tested by a *falling-weight apparatus.* About one-tenth of a gram of the explosive is placed on a small anvil, and a hard steel rod placed on top. A weight controlled by guide rods is allowed to fall on the rod, and the minimum height required to explode the charge is a measure of its sensitiveness.

According to this test the chief military explosives can be arranged in the following order of sensitiveness :—

Mercury fulminate.
Nitroglycerine (liquid).
Lead, copper, and iron picrates.
Dynamite No. 1.
Blasting gelatine.
Dry guncotton.
Smokeless powders (vary).
Chlorate explosives (mining).
Tetryl (C.E.).
Picric acid.
Tri-nitro-toluene.
Ammonium picrate.
Wet guncotton.
Gunpowder.
Ammonium nitrate explosives.

(2) *Brisance* (local shattering effect). — For this test a cartridge of the explosive is placed on top of a steel piston, which rests on a copper cylinder placed on an anvil. The cartridge is detonated from the top by a standard detonator, and the shortening of the cylinder is a measure of the brisance. The military engineer has his own special tests, such as finding what weight of the explosive will cut a standard steel rail, untamped.

As previously explained, the shattering effect is proportional to " volume of gas × heat × velocity of detonation density." The following gives the order for the most important explosives :—

Blasting gelatine.
Dynamite No. 1.
Picric acid.
Tri-nitro-toluene.
Guncotton.
Mercury fulminate.
Chlorate explosives.
Gunpowder.

(3) *Power.*—As previously explained, the powers of different explosives can be compared by exploding a weighed charge of each in a modified bomb calorimeter, and measuring the volume of gas produced and quantity of heat evolved. The results are quite reliable. The best practical direct method of comparing powers is the " Trauzl lead-block test."

Trauzl lead-block test.—A cylinder of lead 200 mm. in height and diameter has a hole 25 mm. diameter and 125 mm. deep bored in it. A charge of 10 grams of the explosive to be tested is put in, and a detonator inserted. The charge is tamped by sand and detonated. The increased volume of the hole is afterwards measured, and is proportional to the power of the explosive. The results are in fair agreement with the bomb calorimeter method. Results are, however, really only comparable with explosives which have approximately the same rate of detonation, and discrepancies are explained in this way.

(4) *Test for stability.*—This is a very important test. All explosives of the organic nitrate class, such as nitroglycerine, nitrocellulose, and mixtures containing them, which include all the smokeless powders, are decomposing from the day they are made. The decomposition proceeds at an accelerated rate, and when it has proceeded to a certain point the heat given out may lead to a disastrous explosion where the explosive is stored in large quantities. This has frequently happened.

Several tests have been devised, some very elaborate, but that most generally useful is the original Abel's heat test. It is applicable to all explosives of the organic nitrate class, but not to aromatic compounds such as T.N.T., picric acid, etc. It depends on the following established facts.

(*a*) During decomposition these organic nitrates give off nitrogen peroxide (NO_2); and

a piece of paper treated with potassium iodide and starch is an extremely delicate test for NO_2, which stains it brown or blue.

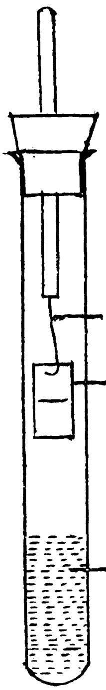

FIG. 7.—ABEL'S HEAT TEST.

(b) An increase of temperature accelerates the rate of decomposition. Roughly, guncotton decomposes as much in one minute at 77° C., as in two years in a store at, say, 15° C.

A standardised apparatus is used for the test, which must be carried out in a specified manner, if results by different operators are to be comparable. Briefly, it is done as follows :—

A small quantity of the finely-divided explosive (1·6 grams for cordite, 1·3 grams for guncotton) is put into a test tube fitted with a rubber cork, through which passes a glass rod ending in a platinum wire with a hook at the end. A piece of the test paper, with its lower half moistened with dilute glycerine, is suspended from the hook so as to hang a short distance above the explosive. The tube is immersed in a water bath kept at a constant temperature (82·2° C. for cordite, 76·6° C. for guncotton), and the time necessary to produce a brown line on the paper is noted, and is a measure of the stability. This must be at least ten minutes for guncotton and thirty minutes for new cordite. Decomposition is so rapid in hot climates, that five minutes will pass a cordite in India.

Figure 7 shows the appearance of the test tube when ready for the test.

RATE OF DETONATION.

This is very important in the case of high explosives, but the apparatus is too elaborate to be described here. Dautriche's comparison method, in which the rate of detonation of a cartridge of the explosive is compared with that of a measured length of detonating fuse filled with T.N.T. having a rate of 6,000 metres per second, is most useful. It will be found described in late standard test-books, such as Marshall's " Explosives."

CONCLUDING REMARKS.

From the foregoing it will be seen that, although enormous work and research is being done, and new mixtures and modifications of old ones are making their appearance every day, there have been no startling discoveries in explosives during recent years. Practically the same explosives are being used by the different nations at war, and none can claim any advantage in that respect.

Also, there does not appear to be much prospect of obtaining more powerful propellants while proceeding on the present lines, as power depends more on heat than on gas, and high temperatures produce excessive erosion of the rifling. With regard to high explosives for shell filling there is still a wide margin, as T.N.T. has only about half the shattering power of blasting gelatine. It should be possible to find some compound equal in power to the latter, and sufficiently insensitive. Possibly a mixture of some substance like tetra-nitroaniline, with a small quantity of another which would reduce its sensitiveness, would answer.

INDUSTRIES AFTER THE WAR.

IV.—TEXTILES (*continued from p. 732*).

Linen.

For the raw material of their industry—flax—linen manufacturers everywhere have hitherto been dependent mainly upon Russia, which contributed 80 per cent. of the total produced. Half of Russia's crop, previous to the war, was exported, a third being consumed by the peasantry of that country, and a hundred thousand tons by Russian mills. Our share was from 70,000 to 80,000 tons. Ten thousand tons are provided by Ireland, and in ordinary times an equal quantity comes to us from Belgium, France, and Holland. The best flax seems to be that received from a Belgian district which has prominently figured in recent communiqués from the Western Front, namely,

Courtrai. In normal times, Courtrai flax fetches from £80 to £100 per ton, Irish £60, and Russian £40. In value Dutch is between Courtrai and Irish. The more superior varieties of the fibre give us our damasks and finer linen. Heavy canvas and sailcloth are made from the coarser kinds grown by Russia. According to the report of the Board of Trade Departmental Committee, the whole amount of flax available for manufacturing purposes is approximately 500,000 tons, made up as follows: Russia, 400,000 tons; France and Belgium, 50,000 tons; Germany and Austria, 30,000 tons; Ireland and Holland, 10,000 tons each. Belgium has the largest consumption (130,000 tons). Germany and Austria are next with 120,000 tons. The United Kingdom utilises 100,000 and France 40,000 tons.

With regard to improving home production, attention is drawn in the report under notice to the well-known and valuable work of the Department of Agriculture and Technical Instruction for Ireland, and the British Flax and Hemp Growers' Society. Additional financial support for research and experiments, the Committee says, should prove profitable, and it is suggested that the assistance already given by the Development Commissioners might be extended with advantage. Further investigation and experiment appear to be needed principally in relation to selecting suitable seeds and manures, artificial retting, etc. Labour-saving machinery is also much wanted, and in this connection the Committee suggests certain amendments of the Patent Laws as a means of encouraging inventors. Canada and India, especially India, are mentioned as promising fields for cultivation on a considerable scale. The Government of India can, it is urged, render valuable assistance by supplying the ryots with good flax seed and by making arrangements for efficient marketing in order to ensure the preservation of the identity of the material in Europe. Flax cultivation should also be encouraged in any other parts of the Empire suitable for its growth. One of the recommendations of the Committee reads as follows: "That the Allied countries should take joint measures to conserve for each other's use in priority to other demands the supply of flax." This, the Committee considers, is the only way of meeting the preparations which the syndication of German linen manufacturers under Government control during the war are making for stronger concentration of effort when peace comes.

Flax-spinning and linen manufacture in these isles are centred chiefly in the north of Ireland, and to a lesser extent in Scotland. Though the industry has suffered, and still suffers, from overproduction, it occupies the third position among textiles so far as exports are concerned. The total annual output is valued at some fifteen millions sterling, and about nine and a half millions' worth are exported. The capital invested in the trade is stated to be about 19½ millions sterling. The following table gives the number of spindles in 1915 and of looms in 1913:—

Country.	Spindles.	Looms.
	1915.	1913.
Ireland	951,912	37,335
England	49,941	4,424
Scotland	160,085*	17,185
Total United Kingdom	1,161,968	58,944

* Including jute spindles.

In thirty-five years a decline of 300,000 in the number of spindles took place. But there was an increase of nearly 50 per cent. in looms, and there still are in existence a great many handlooms, especially in Ireland. The tendency in this trade is towards specialisation and localisation. Thanks partly to the climate, Irish manufacturers produce "the whitest and most beautifully finished fabrics in the world." Before the war, many foreign countries sent their goods to Ireland to be bleached and finished. Owing to the rise in the price of linen, cotton goods "with a linen finish" have been to some extent substituted for the real article. Dunfermline is the centre of the damask trade; Forfarshire of the manufacture of yarns and cloths from Continental flax. Labour conditions are described as not altogether satisfactory, although the operatives in the British linen trade are reputed to be the most skilful in the world. A permanent shortage of labour in Scotland is attributed to low wages. In Ireland complaint is made of irregular attendance and time-keeping, and of a "general lack of ambition on the part of the workpeople." The interesting fact is reported that three years ago the daily working hours in a leading mill in Dunfermline were reduced from nine and a half to eight without any very great decrease in production. Imported yarns are cheaper than Irish, and are said to be of better value. Great efforts have been made within the past few years to recapture the trade by installing more efficient machinery and modifying the flax mixtures. The principal markets abroad for linen goods are the United States and the British Dominions. The value of our linen exports in 1913 was £9,463,500; of our imports in the same year upwards of £2,000,000. The prevailing feeling in the home linen industry is in favour of a graduated scale of duties in manufactured goods, "distinctions being made between Allies, neutrals and enemy countries." In the case of flax yarns, opinion, we are told, is more divided, although there is a considerable demand for "very moderate duties, accompanied by anti-dumping legislation." The trade apparently is unanimous as to future restrictions upon Germany and Austria.

While the British linen industry has not been affected to any great extent by foreign competition

internal rivalry has been very keen in the past, and it appears desirable, the Committee says, that all sections should "recognise the advantage to be derived from common action to meet foreign competition after the war."

(*To be continued.*)

CHANGING CHINESE INDUSTRIES.

The rapidity with which Chinese industries, organised on more or less modern lines for manufacturing goods of foreign style or of foreign interest, has increased in the past few years, has been the subject of considerable discussion in the East, and will doubtless continue to be one of the most important features of Eastern life for some time to come. In a general way it has been the experience of foreign traders in China, as well as in other Eastern countries, that just as soon as a trade in any particular line of manufacture is developed, native factories for the production of such goods are established, the only exceptions being certain industries in which a high degree of skill may be required or where China has no raw materials upon which to work.

For example, soon after the first revolution in China it was confidently expected by many importers that there would be an immense trade in hats and caps to supply the demand for such head-gear, following the change in the style of wearing the hair and the change to foreign-style clothing generally in the open ports. Heavy imports of hats and caps were made, with the result that a large portion of the goods were sold at a loss, for the Chinese, appreciating the force of the demand for the goods, and learning that they could make hats and caps more cheaply than they could import them, started a great number of these factories, and thus supplied the demand themselves. The same has been true of boots and shoes, knitted goods, and sundry other articles. The development of the weaving of finer grade cotton goods, of woollen goods, the manufacture of paper, soap, foreign-style furniture—in short, of practically all lines of goods commonly used by the people—has progressed in a marked way.

As yet, the great mass of such manufacture is in small establishments, using little or no modern power or machinery, and usually depending almost altogether upon Chinese hand labour, but the nature and volume of the output of these concerns as a whole are of the greatest importance, for they are gradually supplanting European and American, and particularly Japanese, goods.

In most lines the increase in such modern manufacture has been more in the variety of products than in volume during the past three years. The war has affected the supply of foreign goods in some lines; high freights have affected practically all lines; while, on the other hand, high freights and the closing of many ports in Europe to Chinese products have so restricted Chinese exports, that producers of export goods have had to turn their attention to other things, with the result that new lines of industry have been developed. In Hong-Kong, moreover, there is always more or less foreign influence, and more or less of foreign capital, in manufacturing enterprises; but, at the same time, even in Hong-Kong, the great majority of all industries are in the control of Chinese capital, are managed and operated by Chinese people, and represent to a large degree independent Chinese progress in industrial development.

Because of war conditions generally, particularly the reduction of the volume of business in nearly all lines due to high freights and to the restricted buying power of most of the Chinese in South China, as a result of their inability to export goods in normal volume, the number of industrial establishments in Hong-Kong has decreased in many lines, although there is a good increase in the total number compared with the number existing previous to the war. In general, however, the more important industries have grown by the increase in the size, equipment, and output of the larger concerns and the elimination of the smaller ones. In all lines the changes are quite significant, and indicate the increasing ability of the Chinese to manufacture "foreign" goods for sale in the markets of the East in competition with similar goods imported from abroad. The Hong-Kong Blue-book for 1916 gives the total number of such establishments listed in the colony as 1,972 in 1916, compared with 1,862 in 1914.

The increase and decrease in the various industries, writes the United States Consul-General at Hong-Kong, measure in a way the course of such industries since the war began. For example, the number of furniture manufacturers increased from 103 to 178, marking the great increase in the use of "foreign" furniture and the increasing necessity of depending upon local manufacture because of high freights as well as high prime cost abroad. The number of tanneries increased from 9 to 13; the number of clock makers from 17 to 21; the number of knitting factories from 17 to 23; of paper-box makers from 18 to 25; of soap factories from 6 to 7; of rope and sail makers from 43 to 130. All these, and other increases, are due directly to the course of demand for "foreign" goods and the increasing ability of the Chinese to supply them. The number of boat-builders declined from 117 to 112, measuring the decreased tonnage of ships entering the port, for these boat-builders are largely employed in making life and other ship's boats for the shipping entering Hong-Kong. Other changes mark changing demand for Chinese goods abroad, or decreased trade due to high freights; for example, bamboo-ware makers decreased from 44 to 25, box makers from 127 to 89, copper-ware makers from 52 to 33, iron founders from 17 to 11, and ironware makers from 149 to 141.

Demand for goods to take the place of foreign-made ware is shown in the increase of tinware

makers from 60 to 90, salt makers from 5 to 25, and brick and tile makers from 22 to 27; in the establishing of a straw hat factory, which was not in existence before. The increased demand for "foreign" goods is illustrated by the increase in the number of bakeries from 42 to 51, while the decreased demand for Chinese prepared foods is shown by the decrease in canneries from 15 to 10, and ginger-packing establishments from 16 to 10. Soy factories increased from 24 to 28. Interference with the receipt of raw materials, high costs, and high freights account for the reduction of vermilion factories, white-lead factories, tin-beating establishments, and dyeing establishments.

Shipbuilding establishments and docks increased from 5 to 8, sugar refineries from 5 to 6, and tin refineries from 10 to 16. These three industries represent the largest establishments in Hong-Kong, with the exception of the cement factories and large rope works, which have been maintained at about their normal standard.

It is of some significance, so far as Hong-Kong is concerned, and to some extent in a general way, that the number of establishments in the "new territories" of Hong-Kong—that is, in the rural districts—increased from 385 in 1914 to 473 in 1916. In other words, the concerns are becoming more closely identified with the more distinctly Chinese portions of the colony.

The development of these industries in Hong-Kong is merely illustrative of a far-reaching development all over China. The industrial world already appreciates the fact that there are large steelworks at Hankow, which can produce probably the cheapest steel in the world; it also appreciates the fact that Chinese cotton-mills have made great advances in the past few years, but in general it does not appreciate that these latter are at the present time turning out increasing quantities of fancy cotton fabrics as well as the standard goods and cotton yarn heretofore produced. The advance made in the manufacture of woollen goods has also been such as to affect the market for woollen products in the East.

Further development in all these lines is unquestionably to be realised in the next two or three years, and the close of the war and the readjustment of trade in the East, following the re-establishing of peace and normal government and financial conditions, will witness an immense change in Chinese industrial and commercial affairs.

AN ARABIAN SOAP SUBSTITUTE.

Although the consumption of soap has largely increased in the Aden district, there is, says the United States Consul at Aden, an important local trade in hottom, which is used as a substitute for soap. Hottom is the Arabic name for the ash cakes which result from the burning of a desert plant that grows plentifully in this part of Arabia.

The plant from which hottom is made is a glasswort or saltwort; both *Salicornia herbacea* and *Salsola kali* are said to be found in this region and used for the purpose. The Arabs call this plant dalook, and say that it is a natural one, because it sprouts from the ground where it would not seem possible that there could have been seeds or any other means of reproduction. As a reason for their belief they point to the parched and barren rocks of Aden from which, when there is one of the rare rainfalls, these plants sprout in great numbers, but usually never to mature. The Arabs of the desert gather these plants and pile them in pits dug in the sand. They are then burned to ashes, the ashes forming a hard cake in the bottom of the pit.

Before the war, when communication with the mainland was free and subject to less interruption than at present, hottom could be had for four annas (4*d.*) per maund of 28 lb. Last year the price had risen to one rupee (1*s.* 4*d.*) per maund. The product reaches Aden by camel caravan from the mainland, one camel carrying from two to three cakes. It is estimated that 6,500 to 7,000 maunds of hottom are sold each year in the Aden market. Much greater quantities are produced and used in the Aden hinterland and in the Arabian Red Sea provinces. The local government levies a tax of a half anna per maund on all the hottom sold in Aden.

The principal purchasers of this product are the native laundrymen (*dhobies*) and dyers. From the former it derives another local name much used by Europeans. Hottom has the appearance of dried cakes of dark mud, and is frequently referred to as "dhobie mud." It is quite effective in washing very dirty or stained clothing, but is said to be sufficiently strong in alkali to have an injurious effect upon the wearing quality of the clothing if used regularly. Hottom is claimed to be an excellent mordant, and the native dyers use it in their work. A large quantity is used in this way.

The plant (dalook) has other important uses. The Arab women gather the branches and leaves and dry them thoroughly. They then crush the dried material into a powder, which is sold in the native bazaars and is also hawked about the streets. The price is one pice (¼*d.*) per cupful, the cup being about one-third of a pint in size. This form of dalook is used for cleansing the body, particularly by the Arab and the Somali women. It is invariably used when the hair receives one of its infrequent washings. The dalook powder is also used to make tough meat tender.

While hottom and dalook are still extensively used, they are slowly giving way to imported soap.

POI-MAKING IN HAWAII.

Poi, made from the bulb of the taro, produced in both wet and dry land areas, and considered the staple dish of the Hawaiians, is still one of the active commercial products of the Hawaiian

Islands, and is being shipped in quantities to the United States, reaching even New York. Taro bulbs weigh from 1 to 3 lb. each, and are usually planted in dyked-in areas, which are kept flooded with water, much the same as in the growing of rice. Broad green leaves project from the bulbs, and are used in the making of "luau," a sort of spinach.

Exports of poi have assumed greater importance in the last six or seven years, largely because of an increasing number of Hawaiians on the American mainland, principally in San Francisco and other Californian cities.

Until twenty years ago, taro was made into poi under more or less primitive conditions. The bulb was pared, then boiled, and placed in a large wooden trencher and pounded with a pestle, a little water being mixed with it in order to get a semi-liquid consistency. When beaten to a mass the product was placed in kegs, and was then ready for sale and consumption.

Poi is considered fresh on the first and second days after it is made, but is commonly preferred when three days old, as a slight fermentation sets in then, giving it a sharper taste. The poi that is made from taro grown in water areas is of either a grayish or a purplish tinge, while that grown in dry-land areas, particularly in the district of Kona, Island of Hawaii, is slightly pink in colour.

According to a report by the Honolulu Correspondent of the United States Department of Commerce, the increased acreage of sugar and pineapple plantations, as well as homesteading in the islands, and the spread of cities into suburbs which formerly were utilised for this plant, have caused the output of taro to diminish. Large areas formerly available are now occupied by suburban residential districts. The decreasing amount of taro, with the continued large demand for poi, caused prices to rise. On the Island of Hawaii the price ranged last year from 8s. to 10s. per 100 lb. Waipio Valley, on Hawaii, is one of the largest taro-producing districts, but the Hawaiians there raise it largely for their own consumption.

Machinery for the making of poi has now come into use, and manipulatoin by hand is almost entirely eliminated, while new requirements of the Board of Health as to the building of factories in which poi is made provide for concrete floors and sanitary methods of manufacture throughout.

The taro root is frequently used in island hospitals for convalescents, or for those whose stomachs are too weak to digest the customary foods.

Five poi factories at Hilo, Island of Hawaii, produce about 2,700 lb. daily. Honolulu has one large machine factory, and several small ones operated by individuals. While this branch of manufacture does not rank in quantity of output with sugar or pineapples, it is one of the most important of the island's interests, as the native Hawaiian usually requires poi for a part of each of his three meals a day.

GENERAL NOTES.

Board of Trade Advisory Council.—Pending the formation of a permanent Council to advise the Department of Commerce and Industries, the President of the Board of Trade has appointed a provisional Council consisting of representatives of various bodies, Government departments and committees, including those on Industries after the War. The Dominion Governments have been invited to nominate representatives. Five Fellows of the Royal Society of Arts are members of the Council, viz., Lord Faringdon (Financial Facilities Committee), Right Hon. F. Huth Jackson (Trade Relations after the War Committee), Mr. L. J. Kershaw, C.S.I., C.I.E. (India Office), Hon. Sir C. A. Parsons, K.C.B., F.R.S. (Electrical Trades Committee), and Sir Frank Warner, K.B.E. (Textile Trades Committee).

Victoria and Albert Museum.—In view of the suitability of monumental brasses as one means of meeting the extensive demands for memorials which have arisen out of the war, a selection of rubbings of well-known English brasses from the Museum collections has been arranged in Room 135 of the Victoria and Albert Museum. The rubbings have been classified under the headings Military, Ecclesiastical, Civil and other Costume, and illustrate the development of this form of memorial in England from the thirteenth century onwards. A few from modern brasses are also shown, including examples from a series now in process of erection upon an "Eleanor" cross at Sledmere, Yorks, in memory of officers and men from that village who have fallen during the war. It is hoped that this exhibition may give an impetus towards reviving the use of a form of memorial which is at once distinctively English in character and admirably suited for the purpose in view.

Market Sought for Capybara Skins.—In the valleys of the Orinoco River and its tributaries are found millions of "chiguires." This animal, more properly called the capybara, is the largest living rodent, and is common throughout S. America from Venezuela to Central Argentine. It is sometimes called the "carpincho" as well as the "chiguire." It is aquatic, inhabiting the marshy banks of brackish streams, and is notorious for the great damage that it does to neighbouring sugar plantations. When full grown the animal is about 4 ft. long and has a girth of 3 ft., weighing nearly 100 lb. The skin is thick and is covered with a rough brown coat of short coarse hair. The animal has a heavy flat head and very short tail. It appears, from a report by the United States Consul at La Guaira, that the chiguires have been officially pronounced undesirable animals, and the Government of Venezuela advocates their extermination. No use for their skins has, however, as yet been found.

JOURNAL
OF THE
ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C. 2.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,440. VOL. LXVI.

FRIDAY, OCTOBER 25, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

COBB LECTURES.

RECENT DEVELOPMENTS IN LEATHER CHEMISTRY.

By Henry R. Procter, D.Sc., F.I.C.,

Emeritus Professor of the Chemistry of Leather Manufacture, Leeds University; Director of the Procter International Research Laboratory.

Lecture I.—Delivered May 13th, 1918.

For the comprehension of advances in leather chemistry, some knowledge not only of the chemistry but of the anatomical structure of skin is required; but, as the latter has been fully described in text-books, it may be very briefly dealt with here. The part of the skin which is converted into leather consists mainly of interlacing bundles of white fibres identical with the connective tissues of the body, and, like them, composed of a tough jelly substance (collagen), which is easily converted into actual gelatine by boiling with water. Interspersed with these, and especially abundant near the outer surface, are yellowish so-called "elastic" fibres of a different chemical nature, insoluble in boiling water, which remain in the leather but appear to take no considerable part in the tannage. Neither the white nor the yellow fibres are really living cells, but cell-products apparently produced by flattened and elongated nucleated cells lying beside them.

In the living animal there is, outside the leather-hide and separated from it by a thin varnish of different nature, sometimes called the hyaline, a layer of living nucleated cells, which form the growing portion of the epidermis, and which as they multiply push the older cells away from their source of nourishment, the blood and plasma of the leather-skin, so that they gradually die and dry up, and finally are removed by friction or washing from the skin surface. From this growing epidermis-layer originate not only hair, horns and nails, but sebaceous glands clustering round and lubricating the hairs, and still deeper sudoriferous glands. Though the hair-bulbs and their accompanying glands are deeply rooted in the leather-hide they are always surrounded by a layer of epidermal cells, continuous with the surface epidermal layer.

Chemically these epidermis products differ in a very marked way from the leather-hide, being nearly insoluble in hot water, and incapable of forming gelatine, but more or less soluble in alkaline solutions or under the influence of certain digestive enzymes. They are all, as far as possible, removed from the skin before tannage, so that it is needless to discuss their chemistry in further detail.

Collagen, the material constituting the bulk of the leather-hide is, as has been stated, closely related to gelatine, of which it is probably merely an anhydride. Gelatine appears to be one of the simplest proteids, its principal proximate constituent being amino-acetic acid (glycocoll), and it contains no groups having a benzene-nucleus. Hence, though a useful proteid food, it is incapable alone of supporting life, since it lacks some of the amino-acids, especially tryptophane, which are now known to be essential.

Fischer's recent researches on the proteids have proved that they consist of more or less complicated chains of amino-acids. An organic acid owes its acid properties to the presence of the carboxyl group $\overset{|}{\underset{\underset{\displaystyle O}{\|}}{C}} - O - H$, to the spare bond of which is attached some hydrocarbon or other organic group on which depends its special character. Thus acetic acid is simply CH_3COOH, butyric $CH_3CH_2CH_2COOH$, while stearic acid has a chain of sixteen CH_2 between the carboxyl and the terminal CH_3. Other acids may have OH groups on the chain or its branches (hydroxy-acids), or one or more phenyl groups C_6H_5 (aromatic acids), so that almost infinite diversity is possible.

Now in place of one of the hydrogen atoms united directly to carbon it is possible to substitute an NH_2 (amino) group; thus amino-acetic acid is $H_2N.CH_2.COOH$; or, looked at in another way, the acetic acid group, less H, is substituted for one of the H's in the decidedly alkaline ammonia NH_3, and the amino-acid is thus a substituted ammonia. The result is a body having both acid and alkaline properties, but very weak in both. Such compounds are called "amphoteric," and it is obvious that the acid head of one molecule can combine with the alkaline tail of another to form a chain; and in this way the proteids are built up. Such chains obviously have a carboxyl-group at one end and an amino-group at the other, and therefore like their constituent amino-acids have both acid and alkaline functions, and this fact accounts for much of their behaviour in the tanning processes.

In preparing skins or hides for tannage the first step is the removal of the hair and epidermis-structures. This is still sometimes effected on sheepskins by a regulated process of putrefaction, in which enzymes produced by bacteria bring the epidermis into partial solution, and so loosen the hair. These enzymes, or "unorganised ferments," are much akin to the digestive principles secreted by the human body, and like these are often very specific in their action, digesting one protein and refusing another. Of course the ideal aim would be to have bacteria of which the enzymes only attack epidermis, and not the white fibrous tissues; and as putrefaction usually begins in the epidermal growing layer, such bacteria are probably at first in excess; but the skins are in anything but sterile condition, and among the mixed millions of bacteria present in a tainted skin there are usually some which attack and injure the skin-tissue itself. The solution of the epidermis is not wholly the work of the bacterial enzymes, but is assisted by the ammonia evolved from the skins by their action, and it has been shown that gaseous ammonia alone will loosen the wool before there is time for any dangerous putrefaction to take place.

A much more important method, and one in almost universal use for heavy hides, is that of treatment with milk of lime. Almost any alkali can be used to loosen hair, but lime has the preference, not merely from its cheapness, but because of its very limited solubility in water, which enables it to be used in great excess without danger, and with the advantage that the dissolved lime, which alone is active, is automatically replaced as rapidly as it is taken up by the hide. If soda were used in quantities equivalent it would produce enormous swelling, and, to obtain the same gentle effect as lime, would have to be almost continuously added in successive small portions, which would greatly increase the labour. From seven to fourteen days and about 6 per cent. of lime on the weight of the hides is required for adequate liming, but much more is often used.

From quite ancient times pastes of lime and realgar, a crude red arsenic disulphide, has been used for the removal of hair, not merely from the finer skins but from the human body. It was shown by Böttger that the effect was not due to the arsenic, but to the calcium sulphydrate formed by its reaction with the lime, and equally good results were obtained from sulphydrate formed by passing sulphuretted hydrogen into lime-milk. Unfortunately the mixture will not keep, and has never been largely adopted. More recently arsenic sulphide has been largely replaced by the much cheaper sodium sulphide, Na_2S; and any of these alkaline sulphide mixtures will reduce hair and epidermis to paste in a few hours without injury to the skin, even if applied in a concentrated form. More usually, however, they are merely added in small quantity to ordinary lime liquors, of which they quicken the action, and so lessen injury to the skin without materially damaging the hair, which is of commercial value. It is worth remarking that orpiment, the yellow arsenic trisulphide, can be quite satisfactorily substituted for realgar, and is often cheaper.

For fine skins, sodium sulphide has never quite taken the place of the arsenic mixture, as it makes a thicker and coarser skin. The cause of this is that, on solution in water, sodium sulphide is resolved into equivalent parts of sodium sulphydrate and sodium hydrate, and the latter has a powerful swelling action on the skin; and if lime is added a still further portion of sodium hydrate is formed. This effect is greatly lessened by the addition of an equivalent quantity of calcium chloride, which, by reaction with the sodium hydrate, forms common salt and sparingly soluble calcium hydrate.

Just as in the case of "staling" the bacterial effect is assisted by the chemical action of ammonia, so in practical liming, the chemical action which would otherwise be very slow is supplemented by the bacteria and their enzymes

which develop in the liquor. While this bacterial action in the limes does, in some cases, lead to injury, it is much less dangerous than direct putrefaction, since many noxious organisms cannot develop in the strongly alkaline liquor. It is singular that when arsenic is used it has practically no antiseptic influence.'

Very recently Dr. Röhm has patented a process in which hair is loosened, not by ordinary chemical means, but by the direct action of the enzymes obtained from the pancreas of animals, and for certain purposes the method seems commercially successful.

Some years ago Messrs. Payne and Pullman patented a process of quick liming, consisting in first treating the goods for twenty-four hours with a 1 per cent. caustic soda solution, which sufficiently swelled and penetrated them, and afterwards for twenty-four hours with an equivalent calcium chloride solution which replaced the caustic soda in the hide by caustic lime. The liming was sufficient and complete, but as the solutions were sterile to bacteria, the goods would not unhair unless they were previously treated in a putrid soak to allow of bacterial action. If the caustic soda be partially replaced by sodium sulphide, bacterial action is no longer necessary.

Though the primary object of liming is no doubt the removal of hair, it has other important and desired effects. The fibre, from its amphoteric nature, combines with the alkali and is much swollen; the fibre-bundles are split up into their constituent fibrils, thus increasing permeability and offering much larger surface to the subsequent tanning process; and more or less of the interfibrillary cementing substance is dissolved and removed. The latter effect renders the leather softer and more porous, and hence is advantageous or the reverse, according to the object in view. It is principally due to the bacterial enzymes, and is therefore regulated to a considerable extent by the age of the liquors and the length of treatment—fresh limes swell the fibre more and dissolve less than old ones.

The hide or skin as it comes from the limes, and after mechanical treatment (now mostly by machines) to remove the hair and epidermis, is a swollen mass of gelatinous fibres containing about 4 per cent. of lime, partly in chemical combination with the collagen. Before tannage, it is necessary to remove this alkali, which would interfere in many ways with the subsequent processes; and if a soft leather is required, not only must the swelling be reduced, but in most cases a further portion of the interfibrillary substance and any residues of epidermis-matter must be dissolved and got rid of. Mere washing with water will only very slowly remove the combined alkali, since the proteid salt merely hydrolyses when the outer solution is nearly neutral, and must be carried out with water practically free of carbonic acid and bicarbonates to avoid precipitation of calcium carbonate in the hide, which is difficult afterwards to remove.

When a firm or only a moderately soft leather is required, the use of acids to decompose the hide-lime compound is now general. By far the cheapest agents are the "strong" mineral acids, hydrochloric and sulphuric, the former having the advantage of a very soluble lime salt. Unfortunately the amphoteric hide is as ready to absorb acids as alkalies, and is equally swollen by them, so that to get good results exact neutralisation without excess of acid is imperative, and to secure this demands intelligent chemical oversight, and hence tanners have largely fallen back on the use of much more costly but safer "weak" organic acids. The sour taste and swelling properties of an acid depend on the concentration of hydrogen ions in its solution, and hence on the completeness of the ionisation, and while hydrochloric acid is almost wholly ionised in dilute solution and all its acidity is exerted at once on the pelt, lactic and acetic acid are only ionised to a very small extent, and consequently swell little; but as the acid is consumed, a further portion ionises and maintains ionic concentration so that in the end as much lime is neutralised as by an equivalent quantity of a "strong" or highly ionised acid.

It is, however, possible to use the "strong" acids with perfect safety if they are added in insufficient quantity completely to remove the lime, and the deficiency is made up with a weak acid; or to a sufficient quantity of the strong acid, the salt of a weak one such as sodium acetate is added so that in either case the operation is completed with the weak acid only.

In the case of sulphuric acid, as calcium sulphate is rather insoluble, it is best to use at once enough of the weak acid to complete the deliming, and afterwards to treat the solution with a calculated quantity of sulphuric acid to precipitate the lime as sulphate, and again liberate the weak acid, when the liquor can be used a second time with only a small

addition of organic acid to make up losses. The economy is worth making, for even at pre-war prices, while 28 lb. of lime could be neutralised with sulphuric acid for 0·8*d.* the same work with acetic acid costs 10*d.*, and with lactic acid 1*s.* 6*d.* Nitre-cake, a crude sodium bisulphate which is now much recommended by the Government as a substitute for sulphuric acid for many purposes, is not suitable for deliming, as in addition to the large quantity of sodium sulphate which it contains, and which lessens the solubility of the lime sulphate formed, it is generally contaminated with traces of nitric and nitrous acids which discolour the leather.

In place of organic acids, boracic acid, which is extremely weak and quite incapable of producing acid swelling, is often used, and the cheap sulphurous acid from burning sulphur deserves more attention than it has received.

In many cases, a simple acid deliming is sufficient even for dressing leathers where extreme softness is not required, and it effects considerable economy in hide-substance as compared to the bacterial and digestive methods which must be later described For this purpose the previous liming should be somewhat long, and conducted in moderately old and bacterial limes to ensure sufficient removal of the interfibrillary substance, and the acids used must be so weak as to produce a minimum of swelling while removing the whole of the lime. This is secured by the use of any weak organic acid, with the addition of sufficient of its neutral salt to repress still further the already weak ionisation, according to the well-known ionisation law. This can be done by using repeatedly, after strengthening with acid, liquors which contain the calcium salt of previous operations. Salts of weak bases with strong acids, *e.g.* ammonium chloride, may also be advantageously used, liberating ammonia only, which has little swelling effect.

The older methods of removing lime and producing the required flaccidity of the skin, depend on the use of somewhat disgusting fermenting mixtures of pigeon-, or, still, worse, of dog-dung. In these the lime is removed mainly by the amino-acids and amine salts, produced by bacterial action, while at the same time the interfibrillary substance and the residues of epidermis and cellular structures are digested and rendered soluble by the bacterial enzymes. The latter action is so strong in the ordinary "dog-puer" at a temperature at 80° to 90° F. at which it is generally used, that in a few hours the entire skin may be dissolved. Undesired bacteria, which are always present, are also apt both to stain the skin and to corrode its texture, so that with the most intelligent management the process is dangerous as well as disagreeable. It may be added that septic and pathogenic bacteria are not infrequent.

The first improvement of this crude method was made by Joseph Turney Wood, to whom we owe most of our knowledge both of the bacteriology and the chemistry of these processes, gained in the limited leisure of a strenuous business career. He prepared a mixed but otherwise pure culture of certain bacteria which produced the necessary depleting effect without injury to the skin, and a suitable culture-medium for it by peptonising gelatinous matter by acids, in conjunction with ground bone, to supply the necessary phosphates. The preparation was produced commercially by him in conjunction with a German firm, and has been used under the name of "Erodin" with a considerable degree of success on calfskins. Wood also showed that a solution of enzymes prepared from puer liquor, with the addition of an amine salt to neutralise and dissolve lime, would produce a satisfactory puering without the presence of any living bacteria. About the same time the suggestion was made that the puer owed its effect to digestive ferments of the dog which had escaped destruction. As all these digestive enzymes are readily putrefiable, and the dog-dung is always kept in a wet condition some time before use, this did not seem inherently probable. But Wood showed that the action could not be due to pepsin, which only acts in acid media, while the working puer-liquor is always alkaline; but that conceivably the pancreatic ferments, which require alkaline additions, might have some effect, and his experiments with pancreatin, an impure trypsin enzyme, gave a somewhat imperfect puering. Wood did not at that time carry the matter further, though he protected the idea in an American patent, but later it was taken up by Dr. Röhm, who, by improved methods of preparation of the pancreas extract and the addition of ammonium chloride to solubilise lime, produced a mixture which under the name of "Oropon" has proved quite successful for calfskins, though for certain uses of sheep, goat, and lamb skins, the practical problem cannot be regarded as wholly solved.

After skins have been puered they are usually "drenched," to cleanse them and remove

residual lime, and occasionally drenching is employed without previous puering. The drench liquor is simply an infusion of bran made with hot water and allowed to ferment either with the skins or before introducing them. The nature of the process has been thoroughly investigated by Wood, who finds that the carbohydrates are first converted into glucose by an enzyme, cerealin, which is naturally present in the bran, and that the glucose is further fermented by bacteria, lactic, acetic and carbonic acids and hydrogen being the principal products. The active bacteria are B. furfuris α and β (Wood), and are possibly originally derived from the puered skins. They are only active in very weakly acid liquors, and die out, without frequent change of medium, from the poisonous effect of the acids they produce, so that the process is, to a large extent, a self-regulated deliming, in which the concentration of the mixed acids is kept constant by their effect on the bacteria. The gases evolved have the effect of floating up the skins at intervals, which are a rough indication of the progress of the operation. The skins, when properly drenched, are white and soft, but no longer quite so flaccid as when they came from the puers. The process is best conducted at about 70° F., and if carried too far the gases evolved in the interior of the skins produce blisters and pinholes, and injurious fermentation from "wild" bacteria may also occur.

It is obvious, from what has been already said, that very much in the tanning process hangs on the property of hide fibres of swelling in acid or alkaline solutions, and "falling," or becoming thin, loose, and flaccid under other conditions; and I must try to give you some idea of what has been recently done to explain these effects, though I admit the subject is an extremely difficult one, and much of the work of myself and my collaborators has not yet found its way into chemical text-books.

I do not know whether I may assume that most of my audience are familiar with the ionic theory, and while time forbids any lengthy explanation, yet without it much of what I am going to say, sufficiently difficult in itself, will be entirely incomprehensible. If atoms are likened to small glass bulbs, each with a definite charge of electricity, positive or negative, sealed inside, it is obvious, on ordinary electrical principles, that the positive bulbs will attract and adhere to the negative, and this, in a very rude way, is a picture of ordinary chemical combination. If, however, such adhering bulbs are placed in a conducting liquid, such as water, their charges will be neutralised by opposite ones condensed on their surfaces, and they will cease to attract each other and be free to move *in* the liquid, though they will recover their attractions if withdrawn from it. Water acts in this way, as an "ionising liquid"—the negative Cl' and the positive Na^+ joined together in solid salt are free to separate within a sufficiently dilute solution; and as all atoms possess the violent vibratory motion we call heat, they tend to separate and diffuse, and exercise pressure, which is called *osmotic*, on the liquid surfaces which confine them. In any solution there is always a definite proportion of such free ions as compared to those which still remain combined, but in "weak" acids and bases, and especially in water itself, this proportion is a very small one.

There is a process known as "pickling," which has sometimes been employed for deliming and as a preparation for chrome and other tannages, as well as commercially, on a very large scale, for preserving wet sheepskins for export. This process involves both swelling and falling, and will in itself convert skin into a sort of leather, so that manifestly its full explanation would throw a good deal of light on the whole theory of tanning.

This process has occupied my attention at times for the last twenty years, and from it I have learned much and hope to learn more, for such an investigation never ends, but always opens up new and often unexpected problems, and the same causes which produce the pickling of sheepskins may be shown to be responsible for some of the most important actions in the human body, and, among others, in all probability for muscular contraction.

The pickling process essentially consists in swelling the skin with an acid, usually in practice sulphuric or hydrochloric (but any acid will do which will cause swelling); and then treating the swollen and gelatinous pelt with a strong solution of common salt in which it "falls," or becomes thin and white, and on being squeezed between the fingers can be wrung out like a rag. We have then a felt of unswollen fibres which do not adhere on drying, or at least may be easily separated by stretching, leaving a very complete white leather, which, however, if placed in water quickly returns to the condition of swollen pelt. I wanted to know why the fibre swelled in acids and why it shrank in salt solutions, for these were obviously fundamental

questions in leather manufacture, and I began my work on sheets of gelatine instead of on actual skin, because they were chemically almost identical, while gelatine was uncomplicated by the capillary structure of the natural fibrous tissue, so that the actual swelling of the jelly itself could be accurately weighed and measured. I used hydrochloric acid for most of my experiments as a simple monobasic acid, identical with that contained in common salt. My first step was to determine the effect on swelling of gradually increased concentration of acid solutions, and at once a singular fact became obvious. The swelling did not increase proportionately to the concentration of the acid, but reached a maximum at a very low concentration (about 1 gramme-molecule in 5,000 litres of water) and then steadily sank with increasing concentration to a point when the acid became strong enough gradually to break up the gelatine chemically, and the experiment could not be further continued. If, however, salt were substituted for further additions of acid no chemical breaking up occurred, and the shrinking could be continued till the gelatine became a horny mass.

When very small quantities of acid only are added to the gelatine it remains at first quite neutral to such indicators as methyl-orange or Congo-red, which react to free acid only, and the acid is evidently neutralised by the gelatine, or, in other words, has formed a gelatine-salt, though as more acid is gradually added there is no sudden change as there would be with soda or lime, and the indicator passes over quite gradually to the acid condition. In former times this was used as an argument that no really definite combination took place, but it is now known that with weak bases, such, for instance, as gelatine or alumina, the salt can only exist in presence of some amount of free acid, without which it breaks up again by combination with the elements of water to re-form the base and acid. Thus a solution of alum is always sour and contains free alumina, and its reaction to indicators is quite gradual.

We have now means of determining the free acid actually present in a given mixture, and as the process (hydrolysis) follows known laws, we can calculate the composition of the neutral salt, or, in other words, the weight of base which will unite with one equivalent of acid can be ascertained. I have calculated in this way the combining equivalent of gelatine as a base as 839, a large value, but much lower than had been previously supposed. The value is probably not quite accurate, but cannot be far wrong. This does not say that the actual molecule is only 839 times the weight of a hydrogen atom, but only that this is the weight of the smallest individual portion of the chemical substance, gelatine, which can exist. At ordinary temperatures, many such chemical individuals may be linked together to one large molecule by what is called polymerisation, but it seems probable that as the boiling-point of a water-solution of gelatine is approached, 839 or some approximate value represents the actual molecular weight.

It must be understood then that every mass of gelatine jelly or every gelatinous hide-fibre in an acid solution of any definite strength is in equilibrium with the surrounding solution, that is that it contains water, gelatine salt, free gelatine, and free acid in such proportions that there is no tendency for either acid or water from the surrounding solutions to pass either into or out of the jelly, though both can pass freely through its surface.

In applying these facts to our problem we may simplify the task to a certain extent by neglecting the un-ionised substances, which in this case affect it only indirectly, and confining our attention to the ions themselves which are the real active agents.

If we admit the existence of gelatine salts, we have to consider the effect of their ionisation on the swelling. The gelatine-ion remains colloid, that is, it tends to agglomerate into masses or large particles which do not diffuse, and consequently exert no appreciable osmotic pressure, while the ionised salt still remains a jelly or a colloidal solution. The Cl ion, on the other hand, tends to diffuse and exerts osmotic pressure, but cannot leave the jelly on account of the electro-chemical attraction of the gel-ion. It therefore swells the jelly, thus drawing into it the outside acid solution. This, however, contains the hydrogen and chlorine ions of the ionised acid in equal quantity, and while the former can enter the jelly without hindrance, the latter is opposed by the osmotic pressure of the ionised Cl already inside. The results are that the acid which enters is less concentrated than that outside, that the concentration of Cl within is greater, and that of H less in the jelly than in the outer solution, and as the acid H cannot enter without its associated Cl, a layer of positive H^+ forms outside the jelly surface, opposed and balanced by a similar layer of negative Cl' within. Thus the two sides of the surface are in different electrical

condition, or, in electrical language, there is a potential between them (Donnan's "Membrane Potential") and the surface layer outside the jelly has a small + electric charge. If, instead of being acid, the jelly and outer solution were alkaline, say with soda, the gelatine being amphoteric would form a sodium gelatinate in place of a gelatine chloride, and the charge would be negative instead of positive. It is obvious that between these conditions there must be an "isoelectric" point of neutrality at which there is no potential charge. This does not necessarily occur at the exact acid and alkaline neutrality of water, but is dependent on the relative acid and alkaline affinities of the individual proteid. In gelatine and hide-fibre, it is slightly on the alkaline side, and this is the point of minimum swelling and greatest flaccidity of the skin, and is generally approximately realised in bating and puering processes which have that aim. With regard to the actual tanning process, these charges are also of the highest importance.

The osmotic pressure tending to swell the jelly is therefore a balance of two opposing forces, that of H^+ pressing in, and of Cl' (or some other acid-ion) pressing out. Donnan has shown that when the jelly and its outer solution are in electrical and chemical equilibrium, the proportions of the two are connected by the law that the H^+ multiplied by the Cl' within the jelly must equal the $H^+ \times Cl'$ of the outer acid. Now the H and Cl of the outer acid are equal, while in the jelly Cl is in excess, and the *sum* of equals is always less that that of unequals which give the same *product*. Thus the *sum* of $4+4$ is 8, that of $8+2$ is 10, yet both give the *product* 16. There is thus always a slight osmotic force tending to swell the jelly, greater as the two factors are more different. The greatest difference occurs when the quantity of free acid is very small and the chlorine in the jelly is almost entirely in the form of gelatine salt, and it is there that we get the greatest swelling. As the concentration of the acid and its quantity in the jelly increases the difference becomes less and the swelling diminishes, and if we add salt also in large excess, as in pickling, both almost entirely disappear.

We have therefore accounted for the swelling force, and shown that as it increases or diminishes the swelling does the same, and not merely in a general way, but mathematically and quantitatively, and that this force only quite disappears when the concentrations become infinite and equal. As, however, the swelling does not go on to infinity and solution, there must be some opposing force, which, when the swelling reaches a definite equilibrium, is equal and opposite to the swelling force. This is apparently the attraction of one gelatine particle for another, the elastic cohesion of the gelatine; and it seems to follow the Hooke's law generally applicable to elastic strains, in that it is proportional to the volume-extension. The exact nature of such strains has not yet been determined, but in the case of colloids it may have much to do with surface tension. That it is sufficient to account even for the intense contraction under the influence of salt is shown by its magnitude when water is withdrawn by ordinary evaporation—a drying film of gelatine will often actually tear away the surface of glass to which it adheres. In another respect it resembles other elastic forces, since it diminishes rapidly and the swelling increases with increased temperature till at the melting-point of the jelly it apparently disappears, and the swelling goes on to complete or colloid solution. As, however, even in solution, the gelatine particles can be shown to retain their electric charges, it is probable that at least at temperatures below 70° C. they still continue as separate particles suspended in a surrounding liquid.

CULTIVATION OF THE CASTOR-OIL PLANT IN COLOMBIA.

Considerable interest is being shown in Colombia, both in the Department of Santander and in the Department of the Atlantic, in the castor-oil plant. This plant has been grown for several years in a small way in Santander, but its possibilities as a money-producer have only recently become evident as a result of the high prices of castor oil. The interest evoked was largely through the discovery of a local druggist, who found he could produce his own castor oil much cheaper than he could import it. The first yield was so satisfactory that others commenced to plant, and at present there are approximately 350 acres under cultivation near Barranquilla (Department of Atlantic), and about 1,500 acres in the Department of Santander.

From a report of the United States Consul at Barranquilla it appears that the Santander bean is larger than that grown on the coast, but is said to yield a smaller percentage of oil. The coast bean gives a yield of 50 to 60 per cent. in oil, while that from Santander gives only 40 per cent.

The plant grows best in sandy soil well watered, but it has been found that too much water is not good for it. Some planting done in land that was almost marshy gave very poor results. The seeds

are planted $6\frac{1}{2}$ ft. apart, and the plant matures in from three and a half to four months. Estimates on the cost and profit of cultivating this bean were based on a yield of 2 lb. of seed per plant per year, but actual results have shown that this yield will be nearer 4 lb.

It is calculated that the cost of planting and harvesting one hectare (2·47 acres) for one year is £8. One hectare contains 2,500 plants which, at the low estimate of 2 lb. per plant, will yield 5,000 lb. of castor beans. At 1*d*. per lb. the crop would be worth £20, leaving a net profit of £12. The price mentioned, however, is much too low, as the seed fetched 2*d*. per lb. last year in Barranquilla.

The harvesting of the crop is done by children, who are sent out daily to gather the ripe pods. These are placed in the sun to dry, and when brittle are broken up by hand. The method is satisfactory at the present prices and on small farms, but the larger growers are interested in obtaining a satisfactory machine to thrash the pods. It is said that such a machine was formerly purchased in England for service in India, but that it cannot now be obtained.

Large shipments of castor-seed meal and of the beans were made last year to New York, and still larger shipments are expected to be made in the future, especially if a satisfactory method of thrashing can be found.

No castor oil is imported into Colombia now, adds the United States Consul, except occasional small shipments of the odourless or aromatic product.

INDUSTRIES AFTER THE WAR.

IV.—TEXTILES (*continued from p. 744*).

Jute.

The raw material of the flourishing jute industry is a monopoly of India, and practically of one part of India. The Board of Trade Committee tells us that cultivation of this, the cheapest of all textile material and certainly not the least durable, is confined to the Presidency of Bengal, the Province of Eastern Bengal, Assam, Cooch Behar and Nepaul; but Sir Charles C. McLeod, in the admirable paper he read before the Society three years ago,* mentioned that an inferior species grown on the Madras side is now in considerable demand owing to improved methods of treatment, better packing, and greater cheapness. As the Committee observes, the cheapness and durability of this fibre cause it to be in constant and universal use throughout the world for the manufacture of sacks, bags, wrappers, and packings for all sorts of raw and manufactured articles of commerce. It is the basis of linoleum and floor-cloths, and is employed in a great variety of other ways. How extensively it has been used for sandbags in the present war is well known.

The question is often asked why in India alone the production of jute is a "business proposition." Higher cost of labour in Egypt and other countries where experiments have been made, unsuitability of soil and climatic conditions, are the reasons given by the Committee in its report. "In India, copious rains alternating with fine weather are essential in the period of growth, and thereafter an abundant rainfall combined with the melting of the snow on the mountains is necessary for the maintenance of the level of water in rivers, ditches and ponds in which the plant must be steeped and retted before the fibre is available for commerce." The area under cultivation is approximately three million acres, though sixty million acres in Bengal and Assam are suitable. That there is not greater expansion is attributed in the report to the market price of raw jute. According to Sir Charles McLeod, the determining factor is labour. The Committee supports the view he put before the Society that a deterioration of quality noted in recent years arises from the fact that enhanced prices have caused the ryots to produce larger crops than they are able to handle. Sir C. McLeod thinks that more scientific methods of cultivation and a careful selection of seeds would double the out-turn per acre. The Committee notes the efforts already made by the Government of India in this direction, and urges further development on the same lines.

The jute crop of 1913-14 consisted of some two million tons, which were distributed roughly as follows: India, 1,100,000 tons; United Kingdom, 300,000; Germany, 160,000; France and America, 120,000 each; Austria, 60,000; Italy and Russia, 50,000 each; Belgium, 20,000; other countries, 20,000.

India has not only a monopoly of the raw article, but is at the head of all jute manufacturing countries, dominating the world's markets in the coarser Hessians, gunny bags, yarns, etc. Dundee had the start of Calcutta by some two decades, and at one time was the sole source of supply for jute goods. The extent of the competition she has experienced since the early seventies of last century is indicated by a table showing the distribution of the Indian crop (in bales of 400 lb.). The figures are as follows:—

	1874.	1884.	1894.	1904.	1914.
Total crop	2,560,000	3,750,000	4,800,000	6,900,000	10,000,000
India	460,000	900,000	2,000,000	2,900,000	5,000,000
Dundee	1,000,000	1,200,000	1,200,000	1,295,000	1,295,000
Continent	300,000	650,000	1,600,000	1,800,000	2,610,000

* *Journal of the Royal Society of Arts*, Vol. XLIV. p. 105.

It will be seen that for some time the industry has been stationary in this country. The Committee was informed that the cost of production, exclusive of raw material, is probably about £12 per ton in Calcutta, as against £25 per ton in this country. Moreover, the Indian mills work from seventy to eighty hours a week, the employees being largely "young persons." Of course, more labour is required to do a given quantity of work than is the case here, but this, it is said, only counteracts to a very limited extent the low wages. It is estimated that in July, 1914, the operatives in the home trade numbered 51,000, of whom only 16,000 were of the male sex. The Indian mills employ about a quarter of a million hands, and the net profit of the various factories in 1913-14 is stated to have been about £1,800,000. From the beginning of the industry Germans largely controlled the distribution of Dundee's goods on the Continent, and it was Germany that erected the first jute-mill outside Scotland. Dundee supplied the machinery, and sent overlookers and operatives "to teach the Germans how to work it." Others followed Germany's example, with the result that by 1879, when the Protective policy of the Continent came into full operation, Dundee had lost the bulk of its Continental trade. "The method adopted," says the Committee, "appears to have been virtually the same in all Continental countries. In the first instance bags were excluded by tariff, and cloth was admitted free. As the industry developed, a duty was imposed on cloth, but yarns were imported free, until finally the satisfactory spinning of jute yarns was achieved, and the market was closed to British goods, with the exception of specialities. The menace to Dundee in the future appears to be that these Continental countries, and especially Germany and Austria-Hungary, are no longer confining themselves to the supply of their home trade, but are beginning to compete in the open markets of the world, notably in the Balkan markets." The following table explains itself:—

Country.	Raw Jute Manufactured.	Retained, per cent.	Exported, per cent.
	Tons.		
India	1,100,000	40	60
United Kingdom	300,000	60	40
France	120,000	75	25
Italy	50,000	80	20
Russia	50,000	100	0
Belgium	20,000	?	?
Germany	160,000	90	10
Austria	60,000	90	10
United States	120,000	100	0

In discussing probable post-war conditions the Committee anticipates that at the conclusion of peace there will come from Germany and Austria alone an immediate demand for at least 300,000 bales. Allied and neutral countries will require exceptional amounts to make up for the shortage caused by the war. Effective control of jute distribution may be regarded, says the report, as one of the most powerful weapons to be held in reserve should the necessity arise for penalising enemy countries or enforcing favourable commercial treaties. In conformity with the views unanimously expressed by the witnesses representing the trade, the Committee recommends the imposition of an export duty (£5 per ton was proposed by experts) on shipments of the raw material from India to all destinations with a total rebate in favour of the British Empire, total or gradual rebates for the Allies, and graduated rebates in the case of neutrals offering reciprocal concessions, a portion of the money derived to be applied towards stimulating production and encouraging more scientific cultivation. It is estimated that the duty would bring in from two to three millions sterling. If afterwards there should still be a deficiency in the supply the remedy suggested is a system of rationing enemy and neutral countries. The demands of British and Allied manufacturers would be met without limit, subject to restrictions upon re-export. It would probably be possible to allow neutrals to obtain the bulk of their requirements for their own consumption, but licences to enemy countries would be restricted to the limited amount after satisfying the rest of the world.

One member of the Committee, Mr. John W. McConnel, disagreed with the "definite recommendation" as to an export duty, on the ground that further inquiry seemed to be necessary. The Committee, it seems, "was not in a position to take evidence as to the needs and wishes of producers and consumers in India." Another member, Mr. Theodore C. Taylor, M.P., was also unable to concur with the majority. *Inter alia* he is of opinion that an export duty would be "unfair to the Indian producer and impolitic as respects our relationship with India."

Those who signed the report without reservation on this or any other point were Sir Henry Birchenough (Chairman), Sir F. Forbes Adam, Mr. James Beattie, Mr. T. Craig-Brown, Mr. Edward B. Fielden, Mr. James W. Hill, Mr. J. K. Kaye, Mr. Edward H. Langdon, Mr. H. Norman Rae, Sir Frederick H. Smith (now Lord Colwyn), Mr. Robert Thompson, M.P. (since deceased), and Sir Frank Warner.

(To be continued.)

THE PEANUT INDUSTRY OF CHINA.

Peanuts are not indigenous to China, having been introduced some time previous to the eighteenth century. They are now grown in all parts of the country except the higher regions.

Chinese peanuts are said to average 46 per cent. oil. The oil is extracted, and exported in large quantities, for use in cooking, as a substitute for olive oil, and largely in the manufacture of soap. The value of peanut oil exported in 1915 exceeded by more than 50 per cent. the value of all peanuts shipped. After the extraction of the oil, the product remaining is formed into cakes, which are used as fodder, poultry-feed, or fertiliser. A large part of the peanuts exported to Europe is used in the manufacture of oil and soap.

The greater part of the peanuts of China used commercially come from the provinces of Shantung, Honan, and Chihli. Shantung peanuts are ordinarily larger in size, while those from Honan and Chihli are said to be somewhat richer in oil, and consequently usually fetch better prices.

Prior to the war the port of Kiaochow (Tsingtau) held first place in exports of both peanuts and peanut oil, shipping, in 1913, 44 per cent. of all the nuts exported and 43 per cent. of the oil. Since then its trade has been diverted largely to Chefoo, Hankow, and Shanghai. Customs returns for 1915 show Tientsin and Chinkiang as the principal export ports for peanuts in the shell. Practically all of these shipments were made, however, to other Chinese ports and Hong-Kong for transhipment and to Pacific ports of Russia. Of peanut kernels Hankow and Shanghai shipped 75 per cent. of the total, the amounts from the two ports being about the same. Those exported from Hankow, however, all went to other Chinese ports—principally to Shanghai — whence they were largely transhipped abroad.

On account of its accessibility to the centres of production and its shipping facilities, Shanghai is the natural port for ocean shipments of peanuts. Large quantities are therefore brought down by local dealers and stored in their godowns awaiting shipment, or else transferred direct from coastwise craft to sea-going vessels. In the latter case the necessary inspections are made at the sources of supply. The former method is considered preferable, in that the exporters have the opportunity to prepare and inspect their cargoes just before the ocean voyage, and to see that proper ventilated storage-space is secured for the shipment.

According to a report by the U.S. Consul-General at Shanghai, the peanut season begins about the end of November and continues to June or July. When the crops are gathered the peanuts are stored in godowns in the vicinity, whence they are shipped as required. No attempt is made to "cure" the peanuts—that is, they are not subjected to any treatment to hasten their hardening, this being left to nature. They soon lose their excess moisture in storage, and it is generally safe to make shipments by the middle of December. It is said that peanuts are likely to get mouldy *en route* if when shipped they contain more than 8 per cent. moisture.

At the points of production peanuts are generally sold as fair, average quality of the season, sound at time of shipment, containing not more than 3 per cent. of stone, mud, dirt, or loose shells. If kernels are sold, the shelling is done at the supply point mostly by hand.

CITRUS CULTIVATION IN SURINAM.

Attention is drawn, in the *International Review of the Science and Practice of Agriculture*, to an article by J. A. Liems on the above subject, published in the *Bulletin* of the Departement van den Landbouw.

There are many orange trees scattered about the plantations in Dutch Guiana, but orange groves have only been formed there more or less recently; the first, planted at Vredenburg, contained 142 trees. Near Surinam is a nine-year-old grove covering about 4½ acres, and another covering nearly 34 acres, composed of native citrus trees from three to eight years old. Other groves have been planted near the Commewyne River. In order to increase the cultivation of citrus trees the Department of Agriculture of the Colony has recently distributed, amongst small holders, a large quantity of grafted orange trees. Of all tropical fruits the orange is the best adapted to export. Exportation was begun in 1907, and since then the local Department of Agriculture has shipped oranges and tangerines to Holland. From the point of view of the prices obtained the results were encouraging. In 1909, 0·24*d.* was obtained per orange sold in Holland; in 1910, ½*d.*, in 1914, 0·36*d.* In 1911, as a result of delay in the departure and voyage of the boat carrying them, the oranges arrived in an unsaleable condition. In 1912, as the crop was poor, no fruit was exported. The experiment was a complete failure in 1913 as a result of the unfavourable shipping conditions. As the boats were not suitably fitted for carrying oranges, a large number of damaged fruit was found in all the shipments to Holland. According to the author, there is no doubt that, when normal conditions prevail again, the shipments may be restarted under conditions favourable to the keeping of the oranges during transport, so that a better price will be obtained for the fruit exported. In Surinam the oranges ripen from July to October, the months during which they are absent from the European market. As Surinam oranges are larger and of better flavour than European ones, they are much in demand on the Amsterdam and Dutch inland markets.

The rules to be observed in sowing seed, care of the seedlings in the nursery, grafting, final plantation (in squares, 25 feet apart, or about 70 trees per acre), cultural methods, etc., are given.

The chief disease is gummosis, found in groves where the trees are too close together. The chief injurious insects are ants, which greatly damage

the orange trees, and scale insects, which attack particularly young nursery plants.

As the cultivation of orange trees is relatively recent in Surinam, it is too early to state which foreign varieties are to be recommended. Lamb's Summer variety produces, in sandy soil, good fruit much appreciated in Europe, but ripening a little late. The Washington Navel orange is less good and less juicy than the native fruit. The Director of the Botanical Garden and the author have sought the best varieties for propagation among the native varieties.

A yield of 1,000 fruit per adult tree is not exceptional. At Vredenburg, in 1911, a tree gave 3,800 fruit. The average yield per tree may be placed at 500 fruit. Estimating the sale price at ¼*d.* per orange, an acre of 65 trees with an average of 500 fruit would bring in about £40; from this must be subtracted the cost of cultivation, placed at about £4.

The methods of packing are described, those used in California for shipping oranges being specially recommended.

COIR-MAT INDUSTRY IN THE PHILIPPINES.

Investigations by the Division Industrial Supervisor for the Province of Pangasinan have been made a basis for the assertion that enough coconut husks are annually wasted in the Philippines to make coir mats with a wholesale value of 22,500,000 dollars. These husks are usually thrown into the rivers and allowed to float out to sea, or they are burned or allowed to rot on the ground. During the year 1916 there were 735,000,000 coconuts gathered in the whole archipelago. The cleaned fibre from the husk of each of these nuts would have weighed approximately 0·22 lb. The fibre or coir from twenty of these nuts would have made a good doormat such as retails in the United States for 1·50 dollars and in the Philippines for two dollars. It is estimated from experience in cleaning this fibre that approximately 80,850 tons of coir might have been realised from the husks of the coconuts grown in the Islands during 1916.

At present, according to a report by the correspondent at Manila of the United States Department of Commerce, only a few hundred coir mats are made in the Philippines, and these are produced by children. Special efforts are being made to develop their manufacture as a household industry in the coconut provinces, particularly in Pangasinan. The industrial departments of the schools are giving special attention to the work. It has been demonstrated that children from eight to twelve years old, with practically no cost for apparatus, can produce mats of good commercial quality. The equipment employed consists of a frame of cheap wood, some bamboo pegs, and a pair of large scissors, or a sharp bolo.

The coir is obtained from the fresh husk of the coconut by pounding it on a log or stone with a mallet or stone, implements which are always at hand. Before the schools, under the direction of the industrial supervisor, took up the manufacture of coir, it was believed that expensive retting vats were needed, and that the retting process would take approximately six months. The experiments in the schools have shown that this long and expensive process is entirely unnecessary. It is the purpose of the Bureau of Education to introduce the making of coir mats among the people as embroidery making and hat making are now carried on in the household. In this way the grower of coconuts may utilise both his material and his time.

There are now fourteen provinces in which 1,000,000 to 9,000,000 coconut trees are bearing. In each of these Provinces, it is estimated, enough unemployed labour is available, if properly organised, to build up a large volume of business in the manufacture of coir mats. The conditions seem to be favourable for employing both home and factory workers in the making of the mats. The coir rope from which the mats are made can be spun rapidly by children of eight to ten years, using a simple contrivance made from a coal-oil box, a wooden roller, and a short piece of coir rope. If there were a central factory in which this coir rope could be used, and a permanent market for it established, the rope could be produced in the coconut centres and despatched to the factory, thereby avoiding the necessity of transporting the whole husk.

Most of the coir mats used in the United States are obtained from Java and Singapore by way of Europe.

EMERALD MINING IN COLOMBIA.

The emerald-mining industry in Colombia dates its origin long before the Conquistadores of Spain turned their eyes towards the Western World. When Bogota was first settled in 1534, the Spaniards made every effort to discover the location of the emerald deposits which were known to exist not many miles from the settlement. Their endeavours were long frustrated by the opposition of the powerful Indian tribes of the district. Finally, however, in 1594 mining operations were begun, the work being carried on wholly by Indian slaves. Great treasures were taken from the district during the Colonial period, a very large portion of the revenues going to the Spanish Crown.

A number of mines were worked by private interests during the first thirty years of the Republic, and fair results were obtained. In 1848, the Colombian Congress decided that thereafter all emerald mining would be carried on under the supervision and for the benefit of the Government, profits to go into the National treasury. This state of affairs continued until 1908-9, when a British company obtained a concession to develop an extensive area. The company was provided with a fair amount of capital and carried on considerable development work, but without

much success. The enterprise struggled along until 1914, when it was deemed advisable to wind up the company's affairs. The mines were taken over by the Government under judgment for £250,000, and the shareholders received back a portion of their investment. Since the outbreak of the war in Europe, and the consequent cutting off of the principal market for the gems, operations have been confined by the Government to the maintenance of the property.

According to a report by Mr. F. M. Halsey, special agent of the United States Department of Commerce, the mines are difficult of access, being three or four days' journey by mule back from the nearest railway. The emeralds are sent through Bogota over the long and expensive rail and water routes to the world's markets.

Colombia is the chief emerald-producing country, the output in a normal year amounting to about 800,000 carats. That the industry is likely long to continue a source of wealth to the Republic is indicated by the fact that, in addition to the already developed field, two new deposits have been located. However, these deposits (at Cosquez and Somondoco) are at present inaccessible owing to transportation difficulties. At least one of the newly discovered fields, adds the special agent, is as rich as the Muzo deposit now being worked.

THE SOUTH AFRICAN OSTRICH INDUSTRY.

Only five years ago the ostrich was the most pampered and highly-valued possession of many South African farmers. Now there is little interest even in the most perfect of these birds.

In 1911, 1912 and 1913 lucerne lands suitable for ostriches, with a good water-supply, were selling at remarkably high figures. A pair of the best breeding ostriches easily sold for £1000. Super-prime feathers (*i.e.* perfect white wing feathers from the cock bird) fetched £24 to £28 a pound on the public market in South Africa. In 1917 the best feathers produced could probably be purchased for £10 to £12 a pound.

It was in the late sixties, writes the United States Consul at Port Elizabeth, that the commercial aspect of the ostrich plume presented itself to the South African farmer. It is probable that the birds had been domesticated on some few farms for many years previous to that time, but about the period mentioned feathers began to be exported to London and thus became a commercial commodity. From a very small beginning the business developed into a trade amounting to hundreds of thousands of pounds annually, but met with a check in 1914, and now there is an almost complete cessation of demand for feathers.

It is difficult to imagine a more ideal existence than that lived by many of the ostrich farmers in the heyday of prosperity. South Africa is properly called "The Land of Sunshine," and except for a brief period in the summer the weather is rarely too hot for comfort. The majority of ostrich farmers are Dutch or of Dutch descent, who naturally prefer country life and open spaces.

When the feather business was at its height farmers gave practically no attention to crops other than the lucerne and mealies that were essential ostrich foods. Even the vegetables required for home consumption were purchased by many ostrich farmers.

As buck and small deer and game birds are found on many of the farms, shooting parties are of comparatively frequent occurrence. This, with his occasional trips to town and interchange of visits with friends, constitutes the usual recreation of the South African ostrich farmer. His home is usually comfortable and frequently quite imposing. Motor-cars are very commonly used in most farming sections.

During the mating season ostriches are decidedly dangerous, attacking a man without hesitation. One kick from the bird's foot is usually sufficient to put any ordinary individual out of action, and several deaths from this cause have been reported. During the nesting period the male and female sit upon the eggs alternately. Broods of eight to fifteen chicks are usual from a sitting of sixteen or eighteen eggs. Incubators are also much used. Ostriches are fed upon alfalfa and mealies, but they pick up a good proportion of their food on the veldt.

On full-grown birds feathers are generally classified as wings, tails, and body feathers. These general classes are graded into numerous varieties to which different names are given. The best long white plumes from the wing of the male bird are termed whites or primes. The latter term is particularly applicable to the best quality whites. Similar feathers from the female are termed feminas; these are white plumes like those from the male, but are usually smaller and generally inferior.

The top row of wing feathers consists of wing blacks or plumes, which are white and black on males and white and grey on females. These are termed byocks or fancies. The second row consists of the whites, or primes, previously mentioned, and are the finest produced. The third row feathers on males are called long blacks, and on females grey. Feathers from under the wing are called floss; body feathers, blacks and drabs or drabby-greys; and the tail feathers are called tails or boos.

There have been previous slumps in ostrich feather prices, but none so serious or so long continued as the present one. Traders admit that the outlook is anything but encouraging. Nevertheless the ostrich feather will come back; it is too beautiful to be long neglected.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Fresh Start.—In one stage of the evolution of a textile industry producers manufacture nothing beyond the plainest of plain cloths, easy to make and certain of sale. The repetition continues until it becomes irksome, when one of more

enterprise than his neighbours ventures upon a line of simple fancy goods, and these serve until they grow stale and are replaced in favour by articles of more novelty. The pace gradually quickens until the pursuit of novelty develops into a race, and the total bulk of the production divides itself into a business in relatively large quantities of the plainer goods upon the one hand, and a more precarious trade in elaborate and expensive cloths, made in an increasing number of patterns, upon the other. During the war the process has been reversed, and industry has been returning, in this respect at least, to the days of its infancy. Textiles have grown plainer, and their range of variety has been reduced to a point beyond which it is almost impossible to get. Starved as the markets are in point of quantity, they may remain for a long while thankful for what they can secure without too nice regard for art or excellence, but sooner or later exfoliation must be renewed. A virtually fresh start has to be made, and it can be submitted that the time and circumstances give an unparalleled opportunity for the direction of taste into right channels. Fashion was never so capable of being moulded, and it is impossible to foresee when any movement for the advancement of industrial art will find so clear a field.

Trade Organisation.—Sir William Priestley, in reference to the Bradford textile trade, recognised within it two sections: the bread-and-butter business on which manufacturers could live but not prosper, and the trade in specialities out of which profits could be made, but the whole community could not be employed. Most manufacturers prefer to retain an interest in both classes, so securing their own position in the event of disappointment. The policy is the mature fruit of seventy years' experience, and Sir William Priestley and others are irked by suggestions that they do not know their interest, and that the future lies with the production of unlimited quantities of common articles. The truth is that large-scale production cannot continue without setting up demand for less vulgarised patterns. The Textile Institute is quite the proper place for a protest against a too mechanical a view of an industry which offers a myriad opportunities to those who are clever enough to seize them. The brutalising influences of factory production are certainly not to be relieved by mere enlargements of scale and the flattening-out of factory products to a uniform mediocrity of style. In a general way what British textile industry wants is more lightness and brightness, greater intellectual agility and scope for individuality. The problem is not one of how to become more like America, or Japan, or Germany—as seems erroneously to be supposed —but rather of how to endue our solid virtues with the sprightliness of France.

Wearing Tests.—Tensile tests are the accepted ones in judging of the capacity of a cloth to resist hard wear, although they manifestly do not tell the whole story. Cloths in use are exposed to other strains than those of a steady pull, and it does not follow absolutely that the fabric showing the highest breaking strain is actually the best wearing. One merit of the test is that at least its results can be recorded with fair accuracy, and it does not appear that this would be possible with the apparatus described as in use by an American clothier. The aim is to reproduce normal conditions of attrition, and for this purpose a surface such as a chair-bottom is taken as a foundation. A specimen of the cloth is stretched over a slightly elastic cushion, and weights are imposed calculated in reference to the area of surface and the normal weight of a man. Eccentric rods give the sample a sliding and rubbing motion, and an indicator records the number of revolutions of the driving shaft. Samples submitted to an equal number of revolutions are then compared with one another, and it is, of course, found that comparative merit does not follow strictly the order of prices. What would be more interesting to know is whether experience gained under these conditions agrees with the judgment formed by moderately expert observers using their unaided senses. Shrewd ideas can be formed from a brief examination of the fibre, the twist of the yarn, and the structure of the fabric. So many factors are present in determining the choice between one article and another that any test restricted to discovery of one feature has necessarily a limited utility in practice. A more ambitious and prospectively more useful device is foreshadowed in the *Textile World Journal* of New York. The writer is busy upon an experimental machine for giving cotton cloths dry friction, representing their treatment in use, and for rubbing them in a wet state, brushing, drying, and ironing them as in laundering. Here again admitted difficulties are met in reproducing all the regular conditions of the washing and drying processes. As irregular conditions, such, for example, as the development of mildew, have to be allowed for, not even such a machine can be relied on to meet all needs.

Aeroplane Cloth.—A sidelight is thrown upon military preparations by the news that 11½ million yards of aeroplane cloth have been let on contract in America by the United States Government, and that deliveries average about 1¼ million yards per month, although the production only began in January last. The cloth is a cotton one, made with long Sea Island fibre, and of a minimum strength of 80 lb. per inch in warp and weft directions. Linen has been superseded in American practice both for practice and combat machines, and the official standard cloth has earned good reports at home and abroad. Joined to the large British production of wing fabric, it is apparent that a great new trade has sprung up, and conceivably one which will not end with the war. The tyre cloth business is present as a reminder

of what changes in modes of travelling may do, and aeroplanes do not need to become as common as motor-cars in order to provide a considerable market for cloth. Cotton, it will be observed, comes unfailingly into direct association with each new development of the times.

GENERAL NOTES.

INDIGO IN THE BOMBAY PRESIDENCY.—Previous to the Indian famine of 1900 some 200 acres of land in the Jambusar taluka, Gujarat, were devoted to the cultivation of indigo. According to a correspondent of the *Times of India*, the local cultivators made a fresh start last year with about thirty acres. "The Surat, Broach, and Kaira districts in Gujarat are," he says, "eminently suited to the cultivation of indigo, and if serious attempts are made in these districts and in the Baroda State to popularise the raising of the indigo-bearing plant, the obsolescent industry will prove entirely successful on a commercial scale in the course of the next few years." It is added that the Bombay Agricultural Department has for some time past encouraged indigo production in the Khandesh and Broach districts. Mr. William Foster, C.I.E., in his paper, "English Commerce with India, 1608-1658" (*Journal of the Royal Society of Arts*, Vol. LXVI. pp. 361-372), mentions that in 1615 the "Hope" took home from Surat, once "the chief export and import centre of India," over 1,400 bales of indigo, and that thenceforward this article became the principal constituent of the cargoes shipped to England from the same emporium. The chief centres of supply were Sarkhej, near Ahmadabad, and Biana, near Agra. In 1652, the Surat factors wrote to the East India Company that "indigo hath heretofore bin your most gainefull comodity."

BRANDED HIDES.—In a paper on the leather trade read before the Coimbatore Agricultural Conference, the author, Captain A. Guthrie, said branding is done in India chiefly for identification, medical and ceremonial purposes, to avert the evil eye, and to render the hide valueless, so as to stop any chance of the animal being poisoned for the sake of its skin. For identification purposes a small brand on the cheek or neck would be effective. He very much doubted if heavy branding stops poisoning, and the value of branding for the other reasons mentioned was also to his mind very doubtful. Indian hides are often very much damaged by carelessness in taking the hides off the carcass. In the case of a sample shown the value had been reduced from Rs. 21 to Rs. 9-8 by flesh cuts. Something like 50,000 branded hides per month came into Madras, averaging a damage of Rs. 4 per hide, so that the monthly loss came to Rs. 2 lakhs. This had reference only to hides good enough to be purchased by the Government. Most of the more badly branded hides do not come in at all, so that the total damage must be much over Rs. 2 lakhs per mensem. The Governor of Madras (Lord Pentland), speaking in the discussion on the paper, said that the real loss was Rs. 3¼ lakhs per mensem. The Agricultural Department had issued bulletins which he hoped would convince owners of cattle of the need for refraining from doing such damage to the hides.

MATERIAL RESOURCES OF BURMA.—Writing in the *Bulletin* of the Imperial Institute, Sir Harvey Adamson, K.C.S.I., lately Lieutenant-Governor of Burma, shows that the material resources of that province are both numerous and valuable. But, while the province has a fertile soil, a rainfall which has never been known to fail, abundant fisheries, magnificent forests, and great though almost unexplored mineral wealth, only three products—rice, teak, and mineral oil—have yet attracted British capital on a large scale. Sir Harvey Adamson attributes this to the comparatively small population, whereby labour is twice as dear as in continental India, and to the inadequate communications; and he advocates a more generous financial policy for the equipment of Burma with roads and railways and other needed public works. Private capital, as well as public funds, can find profitable employment in developing the resources of the country. Sir Harvey Adamson denies that Government is opposed to private enterprise. In the interest of the taxpayer, Government is bound to reserve for itself a fair share of the profits from the exploitation of natural products; but it is always ready to welcome *bonâ fide* applications for concessions from experts or capitalists.

BRAZILIAN PITEIRA FIBRE.—Much has been written concerning the possibility of Brazil developing a large industry in the exploitation of its vegetable fibres. One of the most promising of these fibres appears to be that of the piteira or *Fourcroya gigantea*, because of its adaptability to the making of sacks for bagging coffee. Tests recently made in São Paulo, writes the United States Consul-General at Rio de Janeiro, are said to have been very favourable, and to have shown that the fibre can be used as material for spinning and weaving. It appears to be similar to Manila hemp, both in elasticity and resistance. Potash and wood alcohol are stated to be by-products. Among the various reasons given why this fibre should be produced on a commercial scale are the following: The plant is a native of Brazil, and is adapted to the soil and climate. It lasts from eight to sixteen years, requiring very little cultural attention. From 2 to 3 per cent. of the weight of its leaves is said to consist of fibre, and it gives a considerable amount of alcohol. The piteira may be successfully grown in poor soil. In other words, it is a plant which grows practically unattended in soil of no particular agricultural value.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, at the Society's House, John Street, Adelphi, London, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

PROMOTION OF INDUSTRIAL ART.

A meeting was held at the Royal Society of Arts on Monday, October 28th, the RIGHT HON. H. A. L. FISHER, M.P., President of the Board of Education, in the chair.

[The meeting was originally called to consider a Scheme for the Promotion of Industrial Art, which had been formulated by the Industrial Art Committee of the Royal Society of Arts. After the invitations had been issued, it was found that considerable confusion existed in the public mind as to the claims of this scheme and the Board of Trade proposal to institute a British Institute of Industrial Art. Although the two schemes originated quite independently of each other, it soon became evident that they are really complementary, and it had always been intended that they should work together in close co-operation. To make this clear it was decided to submit both schemes to the meeting, and to issue a joint appeal for subscriptions.

The two schemes will be found printed as Appendices to this report.]

THE CHAIRMAN, in opening the meeting, said: My Lords, Ladies and Gentlemen, we are met here to-day to promote two schemes for the furtherance of industrial art in this country, and although I am neither an artist nor a manufacturer, nor concerned with the distribution of artistic wares, the interests of education and the interests of industrial art are so closely intertwined that I make no apology for taking the chair upon this occasion. The project which we desire to promote to-day is a project which has the support of the Board of Education, of the Board of Trade, and of the Royal Society of Arts, and we propose to issue a joint appeal to the public in support of two schemes which we believe to be conceived in the best interests of industrial art in this country.

Now, the State is by no means indifferent to the progress of the arts and crafts. Already it expends a considerable sum of money upon technical schools, art schools and museums, and it therefore is vitally concerned to see that this public money is wisely and effectively expended. If we ask ourselves the question whether we are at present satisfied that everything which can be done to promote British industrial art is being done, I think we must certainly answer that question in the negative. I think everybody would admit that much more might be done than is done; that much more encouragement might be given to our craftsmen working in isolation and scattered over different parts of the country; that our training in industrial art is susceptible of great improvement; and that much might yet be done to bring the world of industry and the world of art into a closer and more fruitful connection. For we are an artistic people. We are very fond of depreciating our own capacities, and especially of depreciating our own attitude and genius for the fine arts; but I venture to say there has not been a single generation in the whole course of recorded history in which this country has not given indications of its aptitude for artistic productions. The miniatures and the illuminations of this country in the Middle Ages are, if we take the best period, as good as any which have been produced anywhere in Europe. I venture to think that the needlework of this country was better than the needlework of any other country in the Middle Ages; and, even if we make exception of our glorious dynasty of national painters, there has not been a single generation in this country in which we have not shown our capacity for finished accomplishment in the arts and crafts. Although it is perfectly true that since the death of William Morris we have had no supreme master of the arts and crafts, although it is perfectly true that we have perhaps lived too much upon the capital of William Morris's genius, still I think every competent observer knows that this country is rich in craftsmen and rich in designers, and that we have within us the capacity, if that capacity has adequate opportunity, to show the world that we yield to none in the industrial arts and crafts.

The chief purpose of this meeting is to lift our national industries on to an altogether higher level of artistic achievement, by affording encouragement to our designers to obtain first-hand acquaintance with the medium in which they work, and by the formation of a permanent

Exhibition of British Industrial Art, which shall not only offer a stimulus to our craftsmen and designers, but also enable us to obtain a conspectus of the state of contemporary art at any given period of time. One of the schemes before us to-day is a scheme for the establishment of a British Institute of Industrial Art. The Board of Trade, in conjunction with the Board of Education, and with the advice of representative members of the Royal Society of Arts, the Arts and Crafts Exhibition Society, the Art Workers' Guild, the Design and Industries Association, and various persons and organisations connected with manufacture and commerce, have framed a scheme for a British Institute of Industrial Art, and it is proposed that this Institute should be incorporated under the joint auspices of the Board of Trade, as the Department dealing with industry, and of the Board of Education, as the authority controlling the Victoria and Albert Museum. The methods by which it is proposed that our object should be achieved are first of all the establishment of a permanent Exhibition in London of modern British works selected as reaching a high standard of artistic craftsmanship and manufacture. I lay stress upon the phrase "high standard of artistic craftsmanship and manufacture," because, if this enterprise is to succeed, everything depends upon the maintenance of a high standard. Everything depends upon the formation of a jury of selection which shall be stern, censorious, and competent, which will rigidly reject inferior work, and hold up before itself a very high standard of achievement as qualifying for a place in the Exhibition. If this condition is to be realised, if the selection is really to be competent and stern, then it is necessary that there should be a financial guarantee. It is necessary that the jury of selection shall not be subject to anxiety as to balancing its accounts; that it shall not be compelled, through financial need, to accept the offers of firms desirous of obtaining an advertisement of their goods, and willing to pay a handsome price for that advertisement. It is therefore an essential part of our proposal that funds shall be subscribed sufficient to place the Exhibition out of the reach of financial difficulties—at any rate, in the first years of the experiment. In time, no doubt, the Exhibition will pay its way.

In the second place, it is proposed that a selling agency should be attached to the Exhibition, and I think it will be clear to my audience that that proposal is likely to enlist the interests of a great number of manufacturers and industrial producers in this country who might otherwise feel less anxious to exhibit specimens of their artistic products in a London Exhibition. Thirdly, it is proposed that there should be a purchase fund for securing for the State selected works of outstanding merit exhibited at the Institute; and just as the State every year makes certain purchases from the pictures exhibited in the Royal Academy —perhaps not always very judiciously—so it is proposed that certain works of outstanding merit should be purchased by the State from this Exhibition of Industrial Art, and that those works should be placed in the Victoria and Albert Museum. Now, as you are aware, the Victoria and Albert Museum is a wonderful collection of the arts and crafts, not of the present age, but of preceding ages in human history; and I think you will agree that the value of that collection as an educational force in this country, as an active, vital, energising influence over the contemporary arts and crafts, will be very greatly increased if there are placed in the Victoria and Albert Museum specimens of the best contemporary craftsmanship.

It is also proposed that machinery should be established for bringing designers and art workers into closer touch with manufacturers, distributors, and others. I am aware that I am speaking to an audience very much more expert in this matter than I can pretend to be, but I have some reason for thinking that the manufacturers of this country are not quite so alert as are the manufacturers in France to embark upon new artistic designs; and it very frequently happens that quite beautiful and original designs which are presented to English manufacturers are viewed with a considerable amount of suspicion, and that our manufacturers are unwilling to take the artistic risks which are much more freely taken by our brilliant Allies, the French. Of course, part of this may be due to the conservative national temperament, or perhaps to the weak business acumen of our fellow-countrymen, but I think part of it may be due to another cause. I think it is common knowledge that many of our designers, admirable as may be their grasp of the principles of draughtsmanship, are not sufficiently versed in the qualities of the material to which their designs are to be applied, and that it frequently happens—I know this is the case in the textile trade—that a design which looks admirable upon paper, loses, like a translation from Homer, when it is proposed that it shall be transferred to the looms, and that it has, so to speak, to be redraughted and readjusted to the material conditions to which it was originally intended to be applied. The knowledge that many designs good enough on paper are not really suited to the genius and quality of the material for which they are intended, acts as a barrier between the manufacturer on the one hand and the artist on the other, and renders our manufacturers less willing to accept the imaginative creations of the designing world. I take it that it is part of the project of the Royal Society of Arts to encourage, by means of scholarships, and prizes among art students who are taking up this branch of art, a closer and more practical knowledge of the medium with which their art is concerned. After all, it is an impossibility to divorce form and matter in the plastic arts, as it is impossible to divorce form and matter in poetry. Every great and supreme artist has had an intimate and affectionate acquaintance with the qualities and possibilities of the material out of which his art grows.

Among the means which we contemplate for improving artistic education is a closer association with the British School in Rome. This School, which was founded for the study of Roman archæology is, I understand, about to be expanded, and it will become a great institute for the assistance of scholars, students, and artists desiring to make an acquaintance with the artistic legacies of ancient Rome; and arrangements will be made between the British Institute of Industrial Art and the British School in Rome to facilitate Roman studies among English craftsmen and artists.

One word more before I sit down. Although it is true that two Government Departments and one private Society — the Royal Society of Arts — are concerned in this scheme, and are making this appeal to the public, I wish it to be understood that the appeal which we are making is a joint one. It is a joint appeal on behalf of the Industrial Institute on the one hand and of the Royal Society of Arts scheme on the other. The two Government Departments under whose patronage the scheme is to be founded have an equal interest with the Royal Society of Arts in the furtherance of British industrial art, and it is, I think the happiest augury for the success of this enterprise that we have gathered here to-day so many leaders of industry on the one hand and of the arts and crafts on the other.

LORD LEVERHULME: All those who have most deeply at heart the success of the movement that has been inaugurated to-day are to be congratulated upon the presence of Mr. Fisher with us at the meeting, and upon the clear and lucid statement which he has given of the underlying principles which must be borne in mind in endeavouring to make a success of the objects we have in view. We are also grateful to him for calling attention to the fact that we are an artistic nation. No one can dispute the inherent soundness of the British taste for art. I was amused recently at reading a report, dealing mainly with canned fish, made on behalf of a foreign Government, because it was there stated that as soon as the fish-curers and canners paid more attention to artistic labels and designs, wonderful progress was made in the foreign markets. The gentleman who was responsible for that advance was an Englishman, a friend of my own. We are not the backward nation that we are often said to be. Another friend of mine, Mr. Waring, was, as you probably know, commissioned by the Kaiser to furnish his yacht, not in the German taste, but under definite instructions from the Kaiser that the furnishings should be in the British taste of the eighteenth century. The object of the Kaiser, which he so boldly put into effect, was to show those who had the furnishing and the fitting of the great Germanic Atlantic Ocean steamers that we English in domestic taste were ahead of the German race. I am perfectly certain we shall all be agreed that of all styles of decoration the one in which a lady always looks most the lady and a man always looks most the gentleman is the English style of the eighteenth century. Therefore we do start in any campaign of this kind with the right material to work upon, and there must always be an excellent basis for any advance that we are prepared to make.

People who are much immersed in all the details of business are apt to overlook such details as the labels on their packages and even their notepaper and billheads. After all, these are only a connecting link between the producer and the consumer, and surely it is perfectly legitimate to create a favourable impression upon the consumer by means of an artistic, properly designed label, by the best artists of the day, before the package is opened and the quality of the contents can be examined. Any carelessness in this respect on the part of British manufacturers in the past has placed a very heavy and severe penalty upon them. Sometimes the notepaper and billheads are too ornate, containing pictures of medals and so on that have been won at various shows, and these can only create a rather cheap impression. Sometimes they are not only very plain, but poorly printed, so that again a bad impression is created. Therefore the connection of good design—in other words, art—with the question of presenting the goods of the British nation to the great outside world is one that deserves and ought to receive the very closest attention.

When this war is over, we shall have many tasks, and amongst them will be the making of money available for taxation to pay off our war indebtedness. Although those who took a keen interest in the close connection between art and science were in a minority before the war began, when the deluge of the war is over I am certain that they will be in a majority, and that we shall all see the immense value of art and science in developing the resources of the Empire. It will also have an effect in improving the temperament of our workers. Surely it is not a fact that we can be proud of that we have to acknowledge that the mentality of many of our Trade Unionists in this country is such that an Englishman—the finest material the world has produced, who is welcomed as a tradesman, either as an engineer or a carpenter, or whatever it may be, in every country in the world—should be standing, say, on the landing-stage at Liverpool, worth only half the wages that the same man will be worth in a week or ten days' time if he steps on board a boat bound for New York. Now, there must be a reason for this, and surely it will be within the scope of an organisation such as we propose, to raise the mental outlook of our workers so that they see the true reason for it. The reason is this—we have an illustration of it at this very moment close to Liverpool, at Aintree, where a dispute has arisen upon the question of a bonus on output to the workmen—that the outlook of our workmen here in England is limited to narrow confines

bounded by restrictions on output, commonly called "ca' canny," an entirely false view which science and the science of production ought to remove. Suppose an English workman lands in New York, and is engaged by a great engineering firm: if he were to promulgate the doctrines that he had learned from his Union in Liverpool as to restriction of output, he would receive no sympathy from the men across the Atlantic. He would find the Trade Union officials, with Mr. Gompers at their head, repudiating his doctrine as out of date, obsolete, and unscientific. His output would be increased. Instead of being restricted to the use of one automatic lathe, as he would be in England, there would be placed at his disposal as many automatic lathes as he could look after to produce the right quality of goods—perhaps five, six or seven; and instead of receiving, say, the 10*s.* a day that he had been receiving in England, he would receive £1 a day in America. In the one case his output would be costing his employer 10*s.* per machine per day, and in the other case perhaps 4*s.* per machine per day. What wonder is it, then, that, with this false outlook on life, the makers of motor-cars, for instance, in England are outclassed entirely in competition with the makers of motor-cars in America who pay the same workman double wages? And that is the case; it is taking place to-day in the United Kingdom.

I do not want us to feel that this is merely a matter of art in design. It must be art that will broaden the worker's outlook, that will give him something more than a limited view of life, and make him see something in his art which the painter sees in producing his picture. The painter who produces a picture merely with the idea of what the picture will make is, as you all know, a pot-boiler, and he fails to achieve in a very short time even the narrow limited objects he had set before him as his ideal. Similarly in regard to our handicrafts: we must teach our workman to take a pride in his output and production, and, if that were done, the policy of "ca' canny," no matter whether dictated by himself or by his Union, would disappear as morning mists before the rising sun. We have an immense field in this direction. I feel confident that there never was a time when the Empire so needed such guidance as can be given at the present moment, when there are such lessons that it is within its power to learn by means of travelling scholarships, which I am glad to see are part of the scheme, and by close contact between minds that are taking a broader outlook on affairs in general. Let us remember that in all this work we are laying the only solid foundation for reconstruction after the war. Any cheap attempt at doing our business on shallow lines wlll be entirely unsuited for the circumstances of the case when this war is over. We shall start with a handicap, in all probability, of six or seven thousand millions of debt, the interest alone upon which will be a load greater than many people in this room imagined before the war that this country was capable of bearing, apart altogether from the other expenses of Government. We know that it is only by the application of the highest skill and technical knowledge that the best results can be obtained. The progress of evolution will be the same. In the old days poor results were obtained by men who paddled canoes; better results were obtained by the men who first erected a stick on a boat, with a leaf or a palm to act as a sail; later on, better results still were obtained by the men who put in a primitive engine, until we come down to modern times, when the finest results of all have been obtained in our modern Atlantic greyhounds with their turbine engines. The progress that has been made through the centuries has only been possible by the application of the highest knowledge and ability to the utility and the service of man. What the progress may be in the future none of us can realise, but there is in the great wide world the British Empire teeming with wealth only asking to be developed. It cannot be developed by unskilled labour; it cannot be developed without the right tools and the right men, and all this can only be achieved if we train ourselves and others rightly for the task. The London County Council, at the Central School of Arts and Crafts, are making one great advance in training for the art of salesmanship by giving the salesmen and the saleswomen a knowledge of the goods that they have to handle. That is only a beginning. In all other branches we want equally expert knowledge, and with this knowledge and such help as can be given by this organisation I do not think we need be appalled at all by the load of the national debt. Debt is the greatest stimulus you can apply to a human being of the right kind, because there is a natural instinct in the right-thinking mind to clear itself of debt. The existence of a mortgage put upon a home to complete the building or to complete the purchase has probably been a greater stimulus than anything else at a certain period of a young man's life; and I believe that this debt, great as it is, if faced in the right way, with the people of the country trained and developed by such organisations as we are met here to promote, will only be a blessing in disguise. I have very great pleasure in supporting all that Mr. Fisher has said.

Sir Frank Warner, K.B.E.: Although I am deeply interested in both the schemes intended to promote the welfare of British Industrial Art which we have been called together to consider this afternoon, my allotted task is to speak on the British Institute of Industrial Art which it is proposed to establish, and I shall therefore confine my remarks entirely to some aspects of that subject.

At the outset I should like to say that while there is a widespread and natural desire to eliminate Government control of industry at the earliest possible moment, there is at the same time a realisation that the State has functions in connection with industrial development which can be exercised with great advantage. The formation of

the British Institute of Industrial Art is, it appears to me, an excellent example of the part which the Government should play in the promotion and extension of British trade.

It is unnecessary, particularly before such an audience as this, to go at any length into the history of the great improvement in the artistic merit of many of the productions of this country, as that improvement is universally acknowledged; but I may at least be permitted to remind you of the events which in recent years have acted as landmarks in that history.

On the side of artistic manufacture as distinguished from artistic handicraft, the International Exhibitions at Brussels in 1910 and at Turin in 1911 demonstrated beyond dispute that in many branches of industry, particularly in British furniture and decorative art, in pottery and in many kinds of decorative textiles, such as tapestries, silk brocades and velvets, printed linens and cottons, we had made a marked advance in design and colouring, and were, with the exception of France, in certain respects, ahead of all other countries in artistic merit.

At the Ghent Exhibition of 1913 a considerable space was set aside for a display of British Arts and Crafts, and this was so admirably filled and created so much favourable comment that a desire was expressed by the French that it should be repeated in Paris. A portion of the galleries of the Palais du Louvre was cleared for the purpose, and in April, 1914, that ever-memorable exhibition, the contents of which still remain there stored in the cellars, was opened by our King and Queen.

The remarkable interest created and the wide success achieved by these exhibitions led Sir Hubert Llewellyn Smith, Permanent Secretary of the Board of Trade, and Sir Cecil Harcourt Smith, Director of the Victoria and Albert Museum, to write memoranda in which each, without any knowledge of what the other had done, arrived at practically the same conclusion, viz., that there should be established in London, as the capital of the Empire, a permanent Exhibition of Works of Modern British Decorative Artists. These two gentlemen are therefore the originators of the idea, and to them most of the credit is due for the admirable scheme, which I will call the Government scheme, placed before you to-day.

Sir H. Ll. Smith in his memorandum very truly says that "the greatest present need of industrial art in this country is not so much the training of additional artist craftsmen, but the improved organisation of the market for artistic products and the increased appreciation of such products by the public." To-day I am sure he would have gone further and added that it was the "increased opportunity" for such appreciation that was needed, for that is really what the Institute is intended to provide. He also said: "It is notorious that a large proportion of artistic craftsmen have little faculty for commercial organisation; they are scattered and isolated, and liable to be altogether outclassed by the big trading concerns which command the market by reason of their business organisation and commercial enterprise. On the other hand, the purchasing public have little idea of a standard of artistic production, and still less the means of knowing where to lay their hands on the producers of the best artistic work in any particular line. What is needed is an organisation intermediary between the individual craftsmen and the public. This should take the shape of a permanent central exhibition of current works produced by living craftsmen, for sale, subject to the enforcement of a high standard of merit by a selecting committee. Such inquiries as have been made indicate that on the part of artist craftsmen there is a great and growing demand for such an organisation."

It is clear, in my opinion, that if such an organisation were provided, it would not only meet a long-felt and very real want on the part of artist craftsmen and that small section of the public which appreciates their productions, but it would act as a powerful stimulus to the development of the artistic creativeness of our people, and to the fanning into activity of that artistic flame which I am positive is smouldering to a far greater extent than is commonly believed, and which only lacks the necessary atmosphere of encouragement to burn brightly. The Institute would not merely do this, but also provide what I am sure everyone is agreed is much needed—the means of educating public taste and of guiding it on the right lines. This will be an important branch of its work which will find a wide field for its usefulness in provincial centres, as well as in London, as it is obvious that the appreciation of, and the desire for, good things must go hand in hand with the creation of them.

And now I come to the question of the products of the manufacturer, of the firm producing, not the unit by hand, but the thousand by machinery. The manufacturer already has his market, and most of his products are available to the public in the shops, but he is restricted, from an economic standpoint, to those productions which the merchant or distributor will select, and these in turn are guided in their choice by what they believe the public will buy. At times the manufacturer aims at something higher, and produces, frequently at great cost, an article which is different from, and in his opinion better than, the normal marketable article, but he finds in many instances no sale for it. The market to which he is confined may even go so far as to admire it, but will not touch it because the public is not educated up to it.

There are few manufacturers of articles where design or colour, or both, are essentials who have not had their period of enterprise in original or improved production, and have not met with this rebuff. A desire to do something out of the ordinary, to help perhaps some struggling designer of merit, some ambition running riot, or whatever may have been the impulse, has usually resulted in loss and disappointment. Then a definite resolution is made never to attempt anything outside

the boundary of trade requirements; enterprise is quashed; the designer of something possessing original merit is turned down, and a rigid cold shoulder turned to everything likely to be progressive in an artistic sense. Now, this is a condition of things the Institute will do much to remedy. The manufacturer will have a court of appeal before whom he can place his exceptional production. If it is rejected, there is the end of it; if it is accepted by the selection committee, the "cachet" attached to its inclusion in the exhibits of the Institute will alone be a great encouragement, the public will at least see it, and it is more than probable that in most cases the enterprise of the manufacturer will prove to be a success instead of a failure.

There need be no apprehension on the part of wholesale and retail distributors that they will be in any sense supplanted, as it is proposed, in regard to trade productions, that the selling activities shall be conducted on the lines of the British Industries Fair, and certain days will be set apart for accredited trade representatives to meet manufacturers for the purpose of transacting business.

The purchase fund which it is hoped will be provided by the Treasury for securing selected works of outstanding merit for the State is, in my opinion, a most valuable feature of the Institute. Hitherto the best work of a living artist has been allowed to become scattered; some of it passes into private collections, some goes abroad, and the trace of some is entirely lost. When half a century has elapsed, an attempt is made to recover some of these works for our national museums, with the result that the best is either unobtainable or is only purchasable at a price many times greater than its original value. The purchase of such works by the Institute will also form the nucleus of its collection, and in due course these specimens of the best production of an admittedly eminent creator of artistic objects will pass into the keeping of our great national museum for preservation and as examples for the education of future generations.

Hitherto, as is well known, the Victoria and Albert Museum has not been able—owing to want of space—to deal adequately with modern productions of industrial art. It has therefore sometimes been subjected to criticism as an institution dissociated from the life and interests of to-day. The proposed Institute will, it is hoped, establish the essential continuity and remove all ground for such reproach.

The usefulness of the Institute will not end with the opportunities it will bring to craftsmen and manufacturers to extend their activities, nor with the securing of objects of outstanding merit by the State. It will possess and exercise a most important function in bringing designers and art workers into closer touch with manufacturers, distributors, and others who can give them opportunities, which they at present lack, of using their talents to the best advantage. The manufacturer needs people with original ideas and artistic taste; the industrial artist needs the opportunity of putting his activities to practical and profitable use. If the Institute can bring the two together, it will in this respect alone more than have justified its existence.

The opportunity, in view of all that is happening, is for all of us unique and full of great possibilities. Our one outstanding hope of salvation financially is the development of industry on economic and artistic lines. The schemes placed before you to-day concentrate on these vital points. I trust they will be widely approved of and receive your most generous support.

Sir William M'Cormick, LL.D. (Administrative Chairman, Advisory Council, Department of Scientific and Industrial Research): I have been asked to say something as to the relation of this movement to the Department with which I am at present connected—the Department of Scientific and Industrial Research. That Department originated, as most of you know, more than three years ago, in just such a movement as we see at present in relation to art. It was felt that we should pay more attention to the application of science to industry, and that we were not developing on scientific lines as fast as others were, partly perhaps owing to our own fault, and partly owing to the conditions of manufactures and manufacturing in this country. We are all feeling the same now with regard to art, and it occurs to me that I might tell you one or two points of our experience which may be of use in connection with this movement. The first problem we had was to bring the scientific man into connection with the industries. I ought perhaps not to say "the scientific man," because the industrial man is as good a scientific man as what we call the scientific man. We are apt to confine science merely to physics and chemistry, whereas there is also a science of business, a science of costing and of manufacture. But the difficulty was to bring the laboratory into touch with the factory, and the solution we found was to bring the scientific man out of his laboratory and put him into the factory. I was delighted to hear that that was Mr. Fisher's solution to-day with regard to art. Art is not a thing in itself; art is conditioned entirely by its materials, and its technique depends upon these. It is no good taking an artist out of a studio to make a design for some textile such as silk or cotton. He does not know anything about it. He can produce what he thinks is a very pretty design on paper, but he does not know anything of the application of either colour or form to the textile industry. We want to-day to bring the artist out of his studio and put him beside the loom or into the silversmith's shop, where he will learn to understand the material in which he is going to design. It is not merely a matter of the modification of designs that have been made on paper by someone who did not understand the subject; they should never have needed any modification. A design that needs modification is not a true design. It must be a design that

comes out of the brain of the worker who is familiar with the loom and the shop. That should be our central idea in all science.

There is one point which is a corollary of that, namely, that if the movement is to be a success, the initiative for it must come from the industries themselves. We tried to secure that in our scientific movement, and I think in some respects we are hopeful of success. We have had interviews with representatives of thirty to thirty-five of the great industries of Britain, and about half a dozen research associations of the firms engaged in particular industries have already been formed. In connection with those research associations, councils are set up with governing bodies and a director. Not only science and the application of science to the particular industry concerned have been included in their functions, but education also; and there is no reason why these councils that have been formed in the industries for the scientific and educational development of those industries should not also include their artistic development. I think that might quite well be combined with the movement which we have already originated. Might I just give two instances of how closely we are related? The very first research that our Department assisted in was a research in connection with the national pottery trade, and the result of the assistance which we gave them three years ago is that the gentlemen who are engaged upon the research believe that at last they have found the possibility of our making hard porcelain out of British material—a thing that will, if it is workable, probably revolutionise the whole pottery trade of Staffordshire. But the curious thing is this. Probably most of you know that the body in porcelain is the soft clay of which it is made. Now, the body of the new base for this hard porcelain will not stand moulding into the same shapes as those for which china clay is at present used, nor will it take the same colours; so that here you have a new material for industry which you cannot make use of until you bring in the artist as well as the scientist.

Then there is another instance that I should like to mention. We have been asked, in connection with the urgent need for the building of houses immediately after the war, to go into the whole question of the materials, to try if we can find, above all, materials other than wood and bricks — possibly to find through science a means of returning to the old method of cob-building, using the soil on the spot where the house is to be built, with possibly some chemical infusion, and so on. If something like that is found, the whole art of house-building will be conditioned by that material. I do not mean that we are going to build "Art" homes with a capital "A." I was speaking about this the other day to Sir Edwin Lutyens, and he hoped we should not do that, because there is a very grave danger that we may begin to think with a capital "A," and then put "Fine" in front of that letter. I take it that what we are here for to-day is to advance the art of our simple and common every-day life. But that leads to one great difficulty to which Sir Frank Warner has already referred. It is easy, so long as you keep the handicraft, to make experiments in art. The single craftsman tries a thing; he does not succeed; there is no great loss. But experiments in manufacture by the thousand and hundred thousand with our present machinery are another matter. That was really the reason why we asked all the firms in various British industries to combine together. We had the same difficulty in regard to science. The transference of new scientific machinery or a new scientific process from the laboratory to the factory is a very serious and expensive matter. It might not work; it might not be economical: and the same applies to art. As Sir Frank Warner says, a single manufacturer cannot stand the loss of making continual experiments that do not come off. He cannot afford to make hundreds and thousands of art experiments and to have a succession of failures. I suggest that this might be done by the same research associations of which I have spoken, and that they should make the experiments for the good of the industry as a whole. If that were done, your Exhibition and your whole scheme as set forward would admirably adapt itself to such developments as I have indicated.

Sir Charles Allom: In the first place I should like to draw attention to the encouragement which I am sure we have all derived from such a gathering as this. I should think that in the history of industrial art there has never been such a gathering of those who are at the top of the tree in every branch of it. I desire also to thank Sir William M'Cormick on behalf of this Society for the magnificent offer he has made on behalf of the Institution to which he belongs, namely, to make experiments for us. I feel that in the process of carrying through the proposition that we have before us there will be many side issues, and it will devolve, I expect, upon the Royal Society of Arts frequently to take up those side issues and see them through. It will be impossible for any industrial arts body by itself to follow the scientific difficulties which will present themselves from time to time, and such a body as that under the charge of Sir William M'Cormick can attend to them with the greatest care, particularly as it has the greatest amount of money also at its back. The Chairman referred to the question of maintaining a high level of industrial art, and that surely will be one thing upon which we shall focus our minds. It depends in the first place upon the higher education of the artist. While we have in the past had the assistance of the Board of Trade, I feel that never was greater assistance given to us than we have received to-day by Mr. Fisher's presence here on behalf of the Board of Education. The combining of two great Government offices will give us something that we cannot possibly provide through the Royal Society of Arts or any other society which exists. During the recent Exhibitions to which

Sir Frank Warner has referred, we discovered quite definitely that it was impossible for us to run Exhibitions without Government control and help. We now have a combination of two Government Departments, and one can only hope that the education of our artists, which, while it has been the best that we could give them in the direction of their arts, has been lamentably deficient in normal education, will be improved. By that I mean that too frequently our studios have been filled with boys who have come from a class that has been unable to pay for the higher education which universities can give. There are many of us who appreciate how magnificent it would be if this Society could set to work, with the aid of Mr. Fisher, to bring about the possibility of every one of our art students having the inestimable blessings of such an education. We have in this country a Museum second to none in the world, while the art schools are spread all over the country. I know the Museum does a great work in spreading its collections within the reach of the schools of the country, but at the same time we want something more than that. We need, not only in the industrial arts but in all arts and even in architecture, the opportunities which a university training would bring to the higher development of our students. I think, also, too little value has been placed upon the commercial importance of industrial art. It is sometimes forgotten that the country which produces the finest works of art in its shops is the country which holds out an irresistible bait to the richest people in the world. We know how France has benefited from having that bait. It has drawn to Paris nearly every woman who desires to be dressed in the best possible manner. It has drawn every man who was sufficiently rich to buy the most beautiful furniture in the world. On that point I am glad to know that we are gradually attracting from the French markets to the English markets the rich patrons of the decorative arts.

The question of the decorative arts, with which I am most closely associated, reminds me of the immense field of industry that it embraces. The great supremacy of our carpet industry is not only due to the quality of the carpets made, but largely to the influence of the firms who are selling them. If we can not only improve the taste of the heads of firms and the staff that selects patterns, but also enhance the skill of those who sell, you will back up the artists that you employ. I do not lose sight of the fact that a Society like this, with the help of two great Government bodies, has the opportunity of educating public taste, and thereby lifting our artists, by the stimulus of public taste, to a much higher level than they would otherwise reach. Going back over the history of Italian art, many of you will remember what an enormous debt is due to those patrons who provided funds for the artists, enabling them to live; and it is just that development of public taste and of our artists' education that I want specially to draw attention to while Mr. Fisher is with us. All of you must have been somewhat perturbed to notice that a great statesman has recently expressed the hope that he may next year apply a luxury tax. I am extremely anxious about the application of any such tax, because how far an article is a luxury is a very debatable point; and I feel that if a luxury tax is put upon the artistic products of our works a very serious blow will be struck at the supremacy of British industries. We have had held out to us the hope that some of the products of these Exhibitions—which I cannot too devoutly hope will take place—will be housed in the Victoria and Albert Museum. For my own part I can hardly imagine that that magnificent Museum will ever have sufficient room to house the products of our various manufactories, and I should think that a special department will have to be established so that these works may filter through it; and, as time and our efforts to-day influence the evolution of our industrial arts, we shall select the best of them from that great store to go into our museums.

Mr. H. Gordon Selfridge: I desire to endorse both the schemes which this meeting has been called to discuss and those things which have been said in favour of them. To make the idea practicable, however, the consuming public, which must pay its money for better and more artistically produced articles, must be made to know what the more artistically produced articles really are. The public is the jury that settles this thing finally. All of us are more or less lazy. The man who can dispose of his product without extra effort, and without discussion on the part of his customer, is usually going to continue in the same old way and follow the line of least resistance. It is therefore, in my judgment, the duty of those who are directing thought in these islands, and in any other nation, to direct, as far as they can, the great public towards the better and the finer, and make them realise what really constitutes the better and the finer. A permanent exhibition is, no doubt, an admirable thing, but I do not think it is going to create necessarily in itself more artistic products in this Empire. Really, competition within these islands is a very easy affair. I speak with the utmost goodwill—but things come so easily in England, because England has such an enormous consuming public close at hand. People who are doing business in England, and especially in London, with no severe competition, would be driven out of business in very many cities that I could mention if I had time. But things here, as I said, are very easy, and where things are easy the natural result is to make the individual try less hard, and if he tries less hard he will seek the line of least resistance. On the other hand, if we could get the public to insist on something better, to insist upon the good thing and the beautiful thing rather than the just "will it wear?" we should be a great deal better off. It is really a fact—I speak with a certain amount of knowledge on this subject—that the usual customer

inquires of the assistant as to the durability of an article, no matter in what line that article may be. I even fancy that sometimes they ask if a bouquet of flowers will wear. Durability seems to be the chief thing instead of beauty. Most things are really made to throw away after they have lost most of their beauty; but in this country, where durability is such a fetish, people are made to feel that they must wear them until they are worn out, and the duty of those who lead in this project must be to educate the consuming public in that direction. How is that going to be done? I should like, if I could, to see everything in every detail done better in England, and better in London than anywhere else, to see perfection as nearly reached as possible in this great collection of people called "England" or "London." I would love to see the word "satisfaction" eliminated from the dictionary, and everything eliminated that is "quite good enough" if it can be done better. I should like to see the public demand that sort of thing, and then we should see the manufacturers looking round for bright young people of ability, skill and art to make their products better.

How will you educate the public to feel that way? For many years my home was in Chicago—a very active, hard-working sort of city. At one time we had an Exposition, as we call it, there. I differ from Sir Frank Warner in only one point in his excellent remarks, and that is when he said that Exhibitions must be Government-controlled. Personally, I object to the Government controlling anything which can possibly be avoided. A Government which does the work of governing has its hands full. At all events this great Chicago Exhibition, which was really a most beautiful affair, and cost a very large sum of money, was gathered together entirely under the auspices and under the control and direction of the men of business in that part of the world. We built the best buildings that we could; we employed the best architects that we could muster; we filled the buildings with the products of the whole world, gathered together on something like 700 acres of space. It was made a thing of beauty; it was a perfect production of the architects', the manufacturers', the artists' and the industrial managers' skill, and it was really a wonderful education. Chicago is a workshop. It is a great city containing 2½ million people, most of whom have sailed from Europe in the steerage and have come out there to make their daily living, and all those people have had to be brought up to the standard of knowing what life is on really rational lines. Chicago is all the time trying to educate this great crowd of people which has come within her walls to make a living, and nothing has done so much to make those people desire and hunger for the beautiful, to require the better, to be less satisfied with the commonplace, than that great Exhibition which was held for six months in 1893. If we could have in this country, managed, paid for, controlled, directed and advertised by the commercial classes all over this green earth a wonderful exhibition to which everyone, from the least important home in this great community to the very best, could go and learn and enjoy, and then go again and learn more and enjoy further, I think you would find a step of great importance had been taken in teaching the community that the beautiful is better than the commonplace, and that the delightful is better than the cheap.

The Germans learnt one thing in 1876 when they went to the World's Fair at Philadelphia. They sent over there a Government official to make a report to the Government as to the German exhibits that were there, and he made his report in three words—"poor and cheap." The fact that he told the German manufacturers that their exhibits, over which they had taken a great deal of pains, were poor and cheap did more than any one single thing to inspire and force the manufacturers of Germany to get from the common, the ordinary and the cheap, to the better. At all events it had the effect of pulling those people to the best of their ability out of their mediocrity, and putting them into a position of doing things a little better than they had done them before. If we could just dream out a beautiful Exhibition, held where everyone could get at it, in a central location where it was convenient, where it was easy to stroll in, and where everybody could pay a shilling and go in and learn something, I think it would go a long way towards making your most admirably proposed Exhibition a permanent and much-appreciated feature of the people and the manufacturers of this community.

Mr. John Turner (Secretary, National Amalgamated Union of Shop Assistants, Warehousemen and Clerks): I have been asked to say a word from the point of view of the workers with reference to this scheme. I have been wondering what direct part the workers of this country are going to play in this scheme, because I have been almost unable to discover it. Certainly the workers do play a very considerable part in the industrial arts; but, so far as the scheme before this meeting is concerned, there seems to be no corner in it in which they would have any direct opportunity of putting their point of view. There are two things which workers in industrial arts are very largely interested in. Firstly, with reference to the work itself; unless the work is of good quality, the worker can never find happiness in his work. I hope Lord Leverhulme will forgive me when I say that I was wondering how much happiness and how much improvement in industrial art an engineer could get out of working two or three automatic lathes. I wondered how much improvement in industrial art would come from it if he could work a design. It appears to me that any artistic instinct that the man might have retained in him, if he was an engineer and interested in metal, would not be improved by working at an automatic lathe for even four hours a day. His chance would only come at the end of that allotted task,

when perhaps he might begin working by hand on some metal and produce something really artistic which was pleasing to himself and to his fellows. No wonder that a narrow view is taken with reference to the limitation of output on the part of so many Trade Unionists. It is not quite true to say that in America the difference in wages is due altogether to the difference in output. It is partly due to a standard of life which probably has little relation to the output of work. The worker in America sometimes produces no more than the worker produces here, but, owing to the standard of life, he earns considerably more than the worker gets on this side of the Atlantic. But not only will the worker find happiness in his work if the quality is good. The workers are a considerable number in this country, and the very happiness in life of the workers, as well as other people, is bound up in the quality of the goods which are produced. They cannot have happiness in their life without good quality, and therefore the workers in a very large sense will be interested in any scheme that will raise the standard of quality so far as the goods of this country are concerned.

One important point in connection with the scheme is, I understand, that travelling scholarships for designers, for salesmen, and for buyers will be inaugurated. I am very pleased indeed to hear that that is the case, because I have a great deal to do with a body of salesmen and saleswomen. As an organisation we have been affiliated with an international federation of employees on the Continent. The Employees' Association of France have a large number of travelling scholarships, and before the war I had the pleasure of meeting a number of those who came over here, and it was then a cause of sorrow to myself to know that, while people on the Continent could come to England with these travelling scholarships, there was very little reciprocity to send our salesmen and saleswomen abroad to learn from the people there. I am, therefore, particularly pleased to find that it is proposed to give scholarships for designers, salesmen, and buyers, so that in the near future we may be able to reciprocate in that direction. But I still wonder what position the workers will occupy in this scheme. Certainly, so far as they are concerned, the time has come when they should be brought into it directly as workers, and if that can be done I believe it will be for the benefit of all. I do not believe the workers of this country are either very stupid or limited in vision. I believe they will be of service to those who want to promote the scheme, and if a way can be found for them to help, I believe it would be to the advantage of the objects which we all have in view.

THE CHAIRMAN: I regret to say that it is now necessary for me to leave the chair, as I have a Bill to conduct through the House, and I must ask you to excuse me.

MR. A. A. CAMPBELL SWINTON, F.R.S. (Chairman of the Council of the Royal Society of Arts): Ladies and gentlemen, on behalf of the Council of the Royal Society of Arts I desire, before Mr. Fisher leaves the chair, to ask you to accord him a most hearty vote of thanks for his presence here to-day, in spite of his multifarious duties. It has been of the utmost benefit that we have had Mr. Fisher to preside over us.

The resolution of thanks was carried unanimously.

THE CHAIRMAN: Ladies and gentlemen, I am very much obliged to you for the kind way in which you have received the vote of thanks. I only wish that Mr. Gordon Selfridge could persuade the House of Commons that durability should not be the sole test of speaking, because I can assure him that we suffer very much from the prevalence of that doctrine in the Mother of Parliaments.

The chair was then vacated by MR. FISHER and taken for the remainder of the proceedings by MR. CAMPBELL SWINTON.

MISS MAY MORRIS: If arrangements are made for the establishment of a museum or a permanent exhibition, I do urge that a small room should be set apart for the works of William Morris. As the years go by, I begin to realise that three generations have arisen since those wonderful days of 1860 onwards, and that to all the young boys and girls who come on pilgrimage to my house, William Morris is just a great tradition very far away. I should like that tradition to be drawn closer to their lives, and if there was such a permanent record of William Morris's work in the museum or exhibition, that object would be accomplished.

MR. F. V. BURRIDGE (Principal of the London County Council Central School of Arts and Crafts): For better or worse we have no Chicago Exhibition for the elevation of public tastes, but I think we have something in this country which also meets Lord Leverhulme's point when he talked about the doubtful fish that was advertised by good labels. It is my particular mission this afternoon to remind you that none of what you wish to bring about can be accomplished without a due fostering of those institutions which are responsible in this country, at all events at bottom, for the contents of the packages, and those institutions are, I venture to suggest, the schools of arts and crafts. The schools of arts and crafts should be the concern of the Board of Trade as well as of the Board of Education, because they are responsible for educating, in one way or another, the producer, the distributor, and the consumer. We have had teaching in those schools of art men who by their labours are really at the bottom of the scheme that we are considering to-day. Of those men I should like to mention Henry Wilson,

who has thrown a large portion of his life into the development of the very sort of scheme that we are considering to-day. He was the life and soul of the Exhibition in Paris which preceded the war, and which preceded the memoranda that have to a very large extent given birth to this particular movement. This movement is cumulative. It cannot depend upon any one man. The whole of this business is the development of the idea which has always been fostered by the crafts of this country. The manufactures of this country are dependent upon the crafts of this country, and unless we keep the crafts alive by fostering them in every possible way, the manufacturers will lose the basal stimulus on which they depend. The schools of art come into it in this way, that they should be the hotbed for the newer generations of young craftsmen in the same way that they should produce the newer generations both of distributor and consumer. I have been recently particularly concerned with the improvement of the position of the distributor, and I think we ought to pay very great attention to that man. No matter what the manufacturer or the craftsman may produce, he has to reach his public, and if the public is not reachable then he cannot dispose of the great things that he may produce. How is the public reachable? Through the distributor. And the consumer is dependent also upon the distributor, and until we get to the happy time when we can get such a development of public taste as Mr. Gordon Selfridge suggested, we must pay very great attention to the education of the person who stands between the purchaser and the person who consumes. Proper attention has not been paid to that by our authorities and schools; and if our schools will concentrate their efforts on the questions of importance in their particular districts, whether production or distribution, and do not dissipate their energies over an enormous curriculum that cannot be adequately covered, then I think the schools of art which have been erected can do the work that they are supposed to do. The health of this scheme will depend upon the health of the schools of art, on whom is dependent the education of the triumvirate —producer, distributor, and consumer.

Mr. W. Robert Colton, A.R.A.: It seems at the first blush that industrial art is very much divorced from what are commonly called the fine arts, but this I have always thought a great fallacy. Such is the fine gradation between the very greatest products of painting and sculpture, and those products worked into ordinary industrial materials, in moulding and in colour design, that there is no demarcation between the fine arts and the industrial arts. That is one factor which we must recognise if we are to succeed as producers of fine industrial arts. The idea that these arts are different in species and in kind is the one stumbling-block upon which the Board of Education has fallen. Our Government has spent large sums of money on art education, but the period between the time when the designer is trained and the time when he is a practical designer for any species of industrial art manufacture has never been bridged by our Government. It has never succeeded in applying its art-trained product to the real industrial design. That has always seemed to me to be the hiatus between the training and the application. As far as the Royal Academy is concerned, this movement has its every sympathy. It has perhaps in the past been driven along the line of least resistance to have exhibitions of a special sort and species; it is subject to public patronage like any other business or institution; but I think it has shown that it appreciates the future developments in the reconstruction of the trade of this country, and that it is of the highest importance that the industrial future of this country should be very much concerned with the finer development of art of an industrial character. I may remind you that it held a most successful Exhibition recently of industrial art and arts and crafts, and I believe it has every desire to help this great movement in every way in its power. Should this meeting form a scheme which will in any way require its help, the Royal Academy will, I am quite sure, be very glad to appoint a permanent representative from its council upon it.

The Chairman: The hour is getting late, and I propose, therefore, without further remark, to put to you the following resolution which was originally to have been moved by Mr. Fisher had he been able to remain:—"That this meeting cordially commends the scheme of the Royal Society of Arts for the Promotion of Industrial Art, and the Government scheme to establish a British Institute of Industrial Art, and approves the issue of a joint appeal for funds to realise these objects."

The resolution was then put and carried with one dissentient, and the meeting then terminated.

APPENDIX I.

Royal Society of Arts Scheme for the Promotion of Industrial Art.

I. *Objects.*

1. To encourage and co-ordinate movements towards the development and improvement of Industrial Art, with a view to maintaining for the trade of the British Empire its position in the markets of the world; and especially to stimulate closer mutual understanding and confidence between producers, distributors, educational authorities, societies with similar aims, and individuals interested in these aims.

2. To co-operate with Government Departments and other bodies in promoting exhibitions, and in particular with the Government

Scheme for a British Institute of Industrial Art.

[The Exhibitions contemplated would consist of exhibits selected for their artistic and workmanlike qualities, with the intention of stimulating production, commerce, and public taste.]

3. To initiate and encourage research, experimental and other work germane to the objects above indicated; to award grants for conducting such work; and to co-operate, whenever possible, with Government and other institutions founded for such purposes.

[It is considered highly desirable that researches should be made into a large number of materials in order to ascertain exactly their qualities and the uses for which they are most suitable. The qualities of many kinds of timber, *e.g.*, have not yet been scientifically studied.

The Authorities of the Imperial College of Science and Technology and of the National Physical Laboratory have intimated their willingness to co-operate with the Executive Committee of the Scheme for the Promotion of Industrial Art in matters connected with research. With their great staffs of scientific men of the highest distinction, and their admirably equipped laboratories, these institutions offer facilities for work of this kind which are probably unsurpassed.

Another object in view is the award of travelling scholarships to designers, buyers, salesmen, and others, in order to provide them with opportunities of widening their experience and cultivating their taste.]

4. To encourage propaganda work, especially by means of the facilities for lectures and papers afforded by the Royal Society of Arts within the scope of its Royal Charter, "for the encouragement of Arts, Manufactures, and Commerce," and those afforded by other bodies.

5. To raise a central fund to carry out these and such similar objects as may afterwards be determined by an executive committee to be set up at the public meeting to be held in October. The Royal Society of Arts shall be constituted trustee of the central fund.

[Sums given for special purposes by firms, individuals, and societies may bear perpetual designations to associate them with the donors' names, as is the case with other donations and endowments of which the Royal Society of Arts is trustee.

It is suggested that a sub-committee should be set up for each industry which should meet regularly and make recommendations from time to time as to the steps which it is desirable to take in order to promote the interests of that industry. The report of each sub-committee would be submitted to the executive committee, and considered by it both in regard to its general recommendations and to its financial requirements.]

II. *Administration.*

6. The scheme shall be administered by the above-mentioned executive committee, which shall consist of: (1) Persons representing contributors to the central fund; (2) members of the Industrial Art Committee of the Royal Society of Arts, and (3) others engaged in work covered by the scheme.

7. Pending the constitution of this executive committee, the Industrial Art Committee shall act for it.

APPENDIX II.

British Institute of Industrial Art.

The Board of Trade, in conjunction with the Board of Education, and with the advice of representative members of the Royal Society of Arts, the Arts and Crafts Exhibition Society, the Art Workers' Guild, the Design and Industries' Association, and various persons and organisations connected with manufacture and commerce, have framed a scheme for the establishment of a British Institute of Industrial Art, with the object of raising and maintaining the standard of design and workmanship of works and industrial art produced by British designers, craftsmen, and manufacturers, and of stimulating the demand for such works as reach a high standard of excellence.

Organisation of the Institute.

The Institute will be incorporated under the joint auspices of the Board of Trade as the Department dealing with industry, and the Board of Education as the authority controlling the Victoria and Albert Museum, and the methods by which it is proposed to achieve its object include:—

(*a*) A permanent Exhibition in London of modern British works selected as reaching a high standard of artistic craftsmanship and manufacture.

(*b*) A selling agency attached to this Exhibition.

(*c*) A purchase fund for securing for the State selected works of outstanding merit exhibited at the Institute.

(*d*) The establishment of machinery for bringing designers and art workers into closer touch with manufacturers, distributors, and others.

(*e*) The organisation of provincial and travelling exhibitions of a similar character,

either directly or in co-operation with other organisations.

In addition to the governing body, which will be responsible for the general management of the Institute, it is proposed to constitute an independent selection committee, consisting of persons of outstanding reputation and position in relation to design, craftsmanship, and manufacture, and no works will be eligible for exhibition which have not been submitted to and approved by this committee.

It is intended that articles of craftsmanship not intended for multiplication and trade products mechanically produced shall both be eligible for exhibition provided that they comply with the conditions, including those relating to British design and workmanship, and reach the required standard. Probably there will be two sections of the Exhibition for articles of craftsmanship and trade products respectively.

Financial Basis.

It is not at present intended that the Exhibition of the Institute shall be actually opened until after the war, but all preparatory steps are being taken so as to avoid delay when peace has been restored. It is hoped that the Exhibition will be permanently open to the public, except possibly on special days, on which admission may be confined to duly-accredited trade representatives on the lines of the British Industries Fairs. Arrangements will be made for the continual replacement of exhibits that are purchased or withdrawn. A suitable commission will be charged on sales effected through the Institute. There is reason to hope that within a short period of years the Institute may become self-supporting (except, of course, as regards the cost of purchasing for the nation selected works of outstanding merit). But it is necessary to provide for an adequate guarantee fund to ensure the stability of the scheme, at least during its initial stages, and thus to enable a high standard to be rigorously maintained without regard to immediate financial necessities. The Board of Trade confidently hope that such a guarantee fund will be forthcoming.

The above scheme has been framed, and will be worked, in close co-operation with the Council of the Royal Society of Arts, whose own scheme for the encouragement and co-ordination of movements towards the development and improvement of Industrial Art includes as one of its objects the support of the proposed Institute.

MARBLE AND GRANITE INDUSTRY IN VENICE DISTRICT.

Italy is one of the world's most famous sources of supply for both art and building marbles, and marble, granite, and building stones are the common materials used for buildings in that country. Venice is a fireproof city, built of stone of Istria and marble; and the foundations and first courses, at least, of all palaces, public and municipal buildings, Government and business edifices are of these materials.

Venice is immediately adjacent to famous marble quarries with an inexhaustible supply of raw material, worked by cheap labour. The Istrian stone, which is quarried just across the Adriatic, reaches Venice by the cheapest forms of water transportation, being loaded on sailing barges at the quarries, and disembarked at the exact point where it is to be used.

The most important quarries in the Veneto are at and near Verona, the Veronese red and yellow marbles having been favourite building stones since the time when the Colosseum at Verona was constructed. For building, they rank next to the stone of Istria in popularity, and are true marbles, while the stone of Istria is not a true marble, although a very hard limestone, that is much used in Venice because it resists the action of salt water and sea winds.

Besides their value for construction, the Veronese marbles are in great demand for decorative work. Among the names of the several varieties of Veronese marbles are white nembro, coral pink, white peach, partridge eye, yellow snail, yellow azure, and paradise.

A few years before the war a number of famous structures were built or decorated with Veronese marbles. In Vienna the Bourse, the municipal buildings, and the Parliament buildings were adorned with the red, white, and yellow marbles of St. Ambrogio and with stone of Incaffi. The post office at Verona used the red nembro of St. Ambrogio, and the façade of the post office at Zurich is adorned with the red and yellow marbles of St. Ambrogio. Vienna in recent years has made extensive use of Veronese marbles for decorative furniture.

The marbles, writes the United States Consul at Venice, are of excellent quality, and are variegated in hue from the light yellow of alabaster to dark yellow, from ashy to grey, from pale skin-coloured pink to blood red and vermilion, and are also speckled, shaded, spotted, girdled, streaked, veined, piebald, and mottled. They combine lightness with solidity, and are well adapted to the uses of sculpture.

There is a union of marble producers and exporters whose main object is the fixing of prices. This union, formed in 1908, is the Società Anonima Marmifera Veronese (Stock Company of Veronese Marble Producers). There is a similar but larger association, with headquarters at Carrara. In the Verona district there were 201 active quarries in

1913, the same number in 1912, and 207 in 1911. The value of the marble quarried in the rough state was about £32,000 per annum.

The second marble quarrying district in the Veneto is that of Vicenza, which produces the various sorts of "Pietre di Chiampo" and of "Pietre di Valdisole." Large quantities of building stones and marbles were shipped to the United States a few years ago by a Vicenza company. The Genoese marbles are very beautiful but are used only for decorative work, as they crumble easily. The Carrara marbles of the finer quality for use of the sculptors vary greatly in price, according to the dimensions of the block required, as a flaw would often spoil an entire block. Fine quality white Carrara often costs £32 to £40 and more per cubic metre.

GENERAL NOTES.

THE GOTHENBURG FAIR.—The Swedish Fair held at Gothenburg in July bears witness to the rapid development of the commercial energy of Sweden during the war. From having once been the humble vassal of the great foreign markets, Sweden has now progressed so far that she may venture to create an institution comparable to the goods-markets now held in other countries. Dr. Köhler, managing director of the Leipzig Fairs, contributes to *Der Welthandel* (August 2nd) an article, in which he asserts that the sample fair held in Gothenburg between July 8th and 14th may be regarded as highly successful. The fair was visited by some 30,000 persons, and sales to the value of Kr.40 mill. took place.

BOARD OF TRADE ADVISORY COUNCIL.—In the *Journal* of October 18th the names of five Fellows of the Royal Society of Arts who are Members of the Board of Trade Advisory Council were published. The name of a sixth—Sir Gerard A. Muntz, Bart.—was inadvertently omitted.

POTASH AS A BY-PRODUCT.—Replying to a question in the House of Commons on October 24th, Mr. Kellaway (Ministry of Munitions) said that a scheme for recovering potash on a commercial scale from the blast furnaces used in the manufacture of pig-iron was approved last year. In consequence the Ministry had encouraged the installation at various ironworks of gas-cleaning plant designed to extract from the furnace gases potash-bearing dust. Certain of these plants were now in operation, others were under erection, while others, again, were in course of construction. A factory had also been erected at which muriate of potash, free from deleterious impurities, was being manufactured from such dust. This factory was capable of dealing with all the dust that could be collected by the gas-cleaning plants now under erection and construction. As other gas-cleaning plants were installed, it was proposed to erect other factories in suitable localities. A small amount of potash was also being obtained as a by-product of the cement industry, and experiments were at the present time being carried on with a view largely to increase the amount so recovered.

THE EMPIRE'S MINERAL RESOURCES.—The Imperial Institute, in continuation of its publications with reference to the mineral resources of the Empire, has now issued a map with diagrams indicating the sources within the Empire of the chief metals of commercial importance. The outline map shows the occurrence in each British country of important metallic ores, and also the existence of deposits at present unworked. The diagrams attached to the map give for 1915 the production of each country, as well as the total British output and the world's output of each important metal or ore. Among the striking features disclosed are that in the case of gold more than half the total production is within the Empire, the principal producer being South Africa; with silver, the British proportion is rather less than one-fifth, the principal producer being Canada; in the cases of manganese, chromium, tin, and molybdenum, the British proportion is near one-half. It is remarkable that there appears to be scarcely any production of the valuable metals mercury and platinum within the Empire, so that we are almost entirely dependent on foreign countries for supplies.

AMERICAN GUN PLANT IN FRANCE.—The relining of big guns is one of the biggest salvage operations in the war, says the *Iron Trade Review*. The intense heat to which the inner surface of the gun is subjected soon destroys the rifling grooves, and the gun is rendered practically useless, though all other parts are as good as new. When a gun is brought into the shop to be relined, the old lining is first bored out. The jacket is then heated, and the new lining inserted. The gun is next dipped into a shrinkage pit, which shrinks the jacket tightly round the new lining. A large plant for relining the heavy guns in use by the American Expeditionary Force is to be erected in France at a cost of from twenty-five to thirty million dollars. In magnitude it will, it is said, be comparable to the Krupp works in Essen. The plant will include gun-boring lathes, engine-lathes, grinders and rifling machines, extensive shrinking pits, giant travelling cranes, and electric generating plant, a huge boiler-house, and sufficient housing facilities for the whole project. For gun-boring lathe designs for 102 inches swing, there is in construction a giant planer, the base of which is so long that a correction had to be made in the design for the earth's curvature. This base is 500 feet in length.

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C 2

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2)

Journal of the Royal Society of Arts.

No. 3,442. **VOL. LXVI.**

FRIDAY, NOVEMBER 8, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One Hundred and Sixty-Fifth Session will be held at 4.30 p.m. on Wednesday, November 20th, when an address will be delivered by ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council. The subject of the address will be "Science and the Future."

The following arrangements have been made for the meetings before Christmas :—

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. :—

NOVEMBER 27.—LORD D'ABERNON, G.C.M.G., Chairman, Central Control Board (Liquor Traffic), "Liquor Control in Various Countries."

DECEMBER 4.—BENJAMIN SEEBOHM ROWNTREE, "Housing after the War." LORD HENRY CAVENDISH BENTINCK, M.P., will preside.

DECEMBER 11.—MAJOR-GEN. SIR FREDERICK SMITH, K.C.M.G., C.B., F.R.C.V.S., "The Work of the British Army Veterinary Corps at the Fronts." The DUKE OF PORTLAND, K.G., G.C.V.O., will preside.

COLONIAL SECTION.

Thursday afternoon, at 4.30 p.m. :—

NOVEMBER 21.—SIR EVERARD IM THURN, K.C.M.G., C.B., LL.D., "The Present State of the Pacific Islands." SIR CHARLES LUCAS, K.C.B., K.C.M.G., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m. :—

NOVEMBER 28.—BHUPENDRANATH BASU, Member of the Council of India, "Some Aspects of Hindu Life." The Most Hon. the MARQUIS OF CREWE, K.G., will preside.

Papers to be read after Christmas :—

SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S. (Subject to be announced later.)

SIR HERBERT JACKSON, K.B.E., F.R.S., F.I.C., F.C.S., "Trueman Wood" Lecture. (Subject to be announced later.)

FREDERICK WILLIAM KEEBLE, C.B.E., M.A., Sc.D., F.R.S. (Director of Horticulture, Food Production Department), "Food Production by Intensive Cultivation."

B. D. PORRITT, M.Sc., Chief Chemist, North British Rubber Company, "The Rubber Industry—Past and Present."

A. F. KENDRICK, Department of Textiles, Victoria and Albert Museum, "English Carpets."

H. KELWAY-BAMBER, M.V.O., "Railway Transport in the United Kingdom."

LIEUT.-COLONEL H. G. LYONS, D.Sc., F.R.S., "Meteorology during and after the War."

W. L. HICHENS (Messrs. Cammel Laird & Co.), "The Wage Problem in Industry."

SIR FRANCIS TAYLOR PIGGOTT, M.A., LL.M., "The Principles of Design in Japanese Art."

J. W. NORMAN WILLIAMS, "The Hawaiian Islands and their Industries."

J. J. CROWLEY, D.Sc., "The Use of Electricity in Agriculture in Germany."

SIR FRANK HEATH, K.C.B., Secretary, Department of Scientific and Industrial Research, "The Government and the Organisation of Scientific Research."

WALTER LEONARD LORKIN, A.M.I.E.E., "Electric Welding and its Applications."

PROFESSOR JOHN CUNNINGHAM MCLENNAN, Ph.D., F.R.S., "Water Powers and Scientific Development in Canada."

SANDFORD J. KILBY, "Indian Salt Manufacture."

H. KELWAY-BAMBER, M.V.O., "Coal and Mineral Traffic on the Indian Railways."

PROFESSOR H. E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., "Soil Exhaustion in India and its Influence on the Value of Crops."

LORD MONTAGU OF BEAULIEU, C.S.I., V.D. (Subject to be announced later.)

Indian Section.

Thursday afternoons, at 4.30 p.m. :—

January 16, February 13, March 13, April 3, May 15.

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

February 4, March 4, May 6.

Cantor Lectures.

Monday afternoons, at 4.30 p.m. (unless otherwise announced) :—

James C. Philip, O.B.E., M.A., Ph.D., D.Sc., Professor of Physical Chemistry, Imperial College of Science and Technology, "Physical Chemistry and its Bearing on the Chemical and Allied Industries." Three Lectures.

December 2, 9, 16. 5 p.m.

John A. Fleming, M.A., D.Sc., F.R.S., Professor of Electrical Engineering, University College, "Scientific Problems of Electric Wave Telegraphy." Three Lectures.

February 10, 17, 24.

William Arthur Bone, D.Sc., Ph.D., F.R.S., Professor of Chemical Technology (Fuel and Refractory Materials), Imperial College of Science and Technology, "Fuel Economy." Three Lectures.

March 10, 17, 24.

Juvenile Lectures.

Wednesday afternoons, at 3 p.m. :—

Charles R. Darling, A.R.C.Sc.I., F.I.C., Lecturer in Physics City and Guilds Technical College, Finsbury, "Liquid Drops and Globules." Two Lectures.

January 1 and 8.

PROCEEDINGS OF THE SOCIETY.

COBB LECTURES.

RECENT DEVELOPMENTS IN LEATHER CHEMISTRY.

By Henry R. Procter, D.Sc., F.I.C.,
Emeritus Professor of the Chemistry of Leather Manufacture, Leeds University; Director of the Procter International Research Laboratory.

Lecture II.—Delivered May 14th, 1918.

We are now in a position to consider the actual changes of the tanning process, which are partly chemical and partly dependent on the physical process known as "adsorption," which itself may often be merely a surface chemical reaction which cannot be completed in limited time.

So far we have discussed the processes necessary for the preparation of the hide or skin for tanning. It now remains to study its actual conversion into leather. Up to this point, though cleansed and free from extraneous appendages, the hide remains merely raw pelt, wet and easily putrescible, or, if dried, hard, horny, and translucent. Leather, on the other hand, is non-putrescible, opaque, and pliable, when dry, to a greater or less degree.

It is now sixty-five years since Knapp, in a remarkable thesis on "The Nature and Essence of Tanning," gave the first intelligible account of the nature of the change. As has been stated, the raw hide consists of a mass of fibres swollen with water, existing partly in the jelly of which the fibres consist, and partly retained by capillarity between them. If allowed to dry, the loosely-held capillary water evaporates, and the jelly-fibres come into contact while still moist and swollen, and adhere to a solid mass. If on the other hand the fibres can be made to give up the jelly-water while still separated, they no longer adhere, but remain as a fibrous felt with all the physical characteristics of leather. Knapp accomplished this by soaking the pelt in alcohol, in which the fibres are not soluble, and which gradually took the place of the capillary water, and then removed that of the jelly, so that on finally evaporating the alcohol no adhesion took place. Such a leather, if soaked in water, slowly returned to the raw-hide condition, but if a little stearic acid was dissolved in the alcohol it remained as a coating on the fibres and prevented or delayed their re-absorption of water. On these facts he based the theory that the essential of tanning was the coating of the fibres with some constituent of the tanning solution which would make them non-adherent, and he concluded that tanning was a mechanical rather than a chemical process.

Knapp's conclusions were only a part of the truth. He offered no explanation of the causes of dehydration, which, in my view, is an essential part of the operation; and he could not know of the production of permanent leathers by formaldehyde and by bromine, from which no coating substances can be deposited, but which alter the chemical nature of the fibre itself.

Let us first take the tawing or ordinary alum and salt tannage, and consider how far we can apply to it the principles we have already discussed. Aluminium sulphate (which is now generally substituted for alum) partially

hydrolyses on solution into sulphuric acid (hence its sour taste) and alumina which remains in solution (possibly colloidal), with an excess of the normal salt. If hide be placed in such a solution it absorbs the free sulphuric acid and swells, and as free acid is essential to prevent hydrolysis a further portion of acid is liberated and absorbed, and the hydrolysis proceeds much further than it would in absence of the hide, leaving an alumina solution in which the alumina base preponderates over the acid, and which is possibly to be viewed merely as a solution of alumina in the normal salt. Such solutions are known as basic. The swollen leather, if dried in this state, would prove stiff and undertanned, as swollen leather usually is. If, however, common salt be added to the mixture, pickling takes place, the swelling is reduced, and the fibres contracted, so that they dry without adhesion and a sort of leather is formed. These dehydrated and separated fibres now absorb or attract to their very extended surfaces the alumina from the basic solution in which it is very unstably dissolved, which increases the permanence of the non-adhesion. At first this deposition is probably purely mechanical, but if the leather is kept for some weeks under ordinary atmospheric conditions a further change takes place, possibly, as Wilson thinks, a chemical combination to a gelatine-alumina salt, from which the alumina can no longer be completely washed out. If in place of a normal aluminium sulphate solution one is used which has already been rendered basic by the careful addition of soda, the hide does not swell, and the use of salt can be dispensed with, and a somewhat more permanent and more completely-tanned leather results.

Alumed leather is never very resistant to wetting, and chrome leather, which has largely replaced it, is very different in this respect, and if properly tanned will stand even boiling in water without shrinkage, and will remain soft on drying. It was first made by Professor Knapp in 1852, but he, unfortunately, did not perceive its value, and it was left to be re-invented in America by Augustus Schultz in 1884, who produced it by a different method.

Chromium exists in its salts in several different degrees of oxidation, and those of tri-valent chrome are of precisely the same type as those of alumina, and hydrolyse and form basic solutions in a similar way. Chrome alums are the counterparts of alumina alums, in which chrome oxide (Cr_2O_3) is substituted for alumina (Al_2O_3) and in principle basic chrome tannage is identical with alumina tannage, though it yields a much more perfect sort of leather. Chrome alum with sufficient salt will produce a lightly-tanned but very pliable leather, but in practice basic solutions are always used, salts of the empirical formula, $Cr\left\{\begin{matrix}Cl_2\\OH\end{matrix}\right.$, or the corresponding sulphates being generally suitable, though for special reasons more or less basic solutions are often employed. Chrome salts are manufactured from chrome iron-ore, by furnacing with potash or soda, or with mixtures of these and lime, which yields a series of crystallisable yellow chromates, in which chromium trioxide acts as acid, precisely in the same way and with the same type of formula as sulphur trioxide in the sulphates and sulphuric acid. So also as SO_3 forms bisulphates with half the amount of base, CrO_3 forms bichromates, and these are the forms in which it occurs most abundantly in commerce. Bichromates readily give up three atoms of their oxygen, and hence are largely used as oxidising agents in dye-manufacture and similar industries, and the reduced chromate yields crystallised chrome-alum which is thus often something of a by-product.

Hence for tanning purposes it is convenient, according to the market, sometimes to start with chrome-alum, sometimes with bichromate, according to which is cheaper. In the case of chrome-alum all that is needed is to dissolve it in water, and then add gradually, and with constant stirring, a solution of ordinary washing soda, 25 to 30 per cent. of the chrome-alum used. Gradual mixture is essential, or the Cr_2O_3 precipitates, and will not redissolve. I published this process in 1898, and it has been largely used, but another formula I gave a year earlier, starting from bichromate, has also been very successful. In the latter the bichromate is dissolved in warm water, a quantity of sulphuric or hydrochloric acid, calculated to leave the desired basicity, is added, and then sugar or glucose. A violent oxidation sets in—some heat, and large quantities of CO_2 are produced, and the orange-yellow solution rapidly changes to a dark blue-green tanning liquor. Some aldehydes are also formed, which take part in the tanning, and yield a slightly softer leather than the chrome-alum liquor. A curious circumstance noted in this connection is that under some conditions a liquor results which is purplish instead of blue-green, and will not tan properly. A further investigation has revealed that this was due to the formation of

saccharic or some other dihydroxy acid, and to the further discovery that the salts of dihydroxy acids, and especially Rochelle salt (sodium-potassium tartrate), have the power of completely redissolving the chrome from chrome leather, and again reducing it to the state of raw pelt, a fact not without its technical uses.

At the present time both chrome-alum and every form of glucose or sugar are scarce and costly, and it becomes desirable to devise some other mode of preparing chrome-tanning liquors. I find that if sulphurous acid gas, either pure or mixed with air, as from burning sulphur, is passed into a solution of bichromate till it smells of burning sulphur, a tanning liquor, or "chrome extract," is produced of suitable basicity for sole-leather, and which merely requires dilution. I publish this method now for the first time. A solution of sodium bichromate of 4 lb. per gallon of water gives an "extract" of about 18½ per cent. of Cr_2O_3. The equation is—

$$Na_2Cr_2O_7 + 3\ SO_2 + OH_2 = Na_2SO_4 + 2\ Cr(OH)SO_4$$

if the reaction is complete.

The tannage with such liquors can be done either by suspension in pits of liquors of gradually-increasing strength in about three or four days, or in rotating drums like churns, in a much shorter time and without difficulty.

I mentioned earlier that Schultz, in 1884, invented a different chrome-tanning process, and its principles will now be easily understood.* It is generally known as the "two-bath" process in distinction from the single-bath method just described. The prepared skins are first treated in an acidified bath of bichromate (practically one of dilute chromic or dichromic acid). This has no tanning effect, but the skins take up the free acid, and are coloured bright yellow throughout. Only the free acid is absorbed, and a good deal of bichromate is often left in the bath, and sometimes thrown away.

The skins are now transferred to a reducing bath, generally of acidified sodium thiosulphate ("hypo"), containing free thiosulphuric acid and sulphurous acid, and it is here that the actual tannage takes place, the dichromic acid being reduced in and among the fibres to a tanning basic salt. The reducing process is chemically a very complex one, varying with the amount of acid used, and the rapidity of its addition, and even affected, as Stiasny has shown, by the trace of arsenic sometimes present in sulphuric acid; but free sulphur is regularly one of the products, and this, deposited between the fibres, tends to produce fulness and softness of the leather, which is usually also of a lighter colour. In spite of its more complicated character, the two-bath method is quite as rapid as the one-bath, since the materials employed are all crystalloids, and diffuse into the skin more rapidly than the partially colloid one-bath liquors.

The hides or skins, having been converted into leather by either of the processes described, still contain free acid and chrome-salts not sufficiently basic to be permanently fixed. This is remedied by "neutralisation," which consists in treating the skins with a weakly alkaline solution, so as to bring all the chrome present into a sufficiently basic state. If, however, *all* acid is removed from the chrome-salt, so as to leave Cr_2O_3 only, it appears to lose its tanning effect, and the skin becomes hard and pelty, so that considerable caution, and the use of alkaline solutions sufficiently weak completely to penetrate the skin without overhardening the surface, are essential. Weak solutions of borax are frequently employed, but even these have a hardening effect if used too freely, and a solution, proposed by Stiasny, of about 2 per cent. of ammonium chloride or sulphate and 2 to 4 per cent. of washing soda, is much better, as it can be so adjusted as to give the requisite neutralisation without danger. The soda, of course, decomposes its equivalent of the ammonium salt, giving free ammonia, and the alkalinity of this already weak base is further reduced to any required extent by the presence of the neutral ammonium salt, which by a well-known law diminishes its ionisation.

It is not essential that the interior of the skin should be fully neutral, as this is secured by a succeeding process, that of "fat-liquoring." The fat-liquor is a solution of a nearly neutral soap, in which a small quantity of oil is emulsified, and in which the skins are drummed. The oil and soap penetrate, coat, and lubricate the fibres, giving softness and additional water-resistance, and convert any remaining traces of unfixed chrome into insoluble chrome soaps. If the surface is insufficiently neutralised, such soaps are formed outside the skin, and adhere to it as a sticky

* In his original process Schultz added only about two-thirds of the hydrochloric acid necessary for the complete liberation of the chromic acid of the bichromates, and, for some reason incompletely understood, the best results are not obtained when the exact theoretical quantity is used. Eitner has, however, got good results by using acid somewhat in excess of the theoretical amount (equal parts of bichromate and 33 ozs. hydrochloric acid), and such a bath can be exhausted by a second lot of skins. Skins are also frequently pickled before chroming.

mass, which renders the subsequent dyeing and finishing impossible.

Chrome sole-leathers are not usually fat-liquored, and sometimes not even neutralised, but are dried out and impregnated with a melted mixture of waxes and rosin, which gives firmness and water-resistance.

Several other mineral tannages are possible, and especially those with iron, which forms salts analogous to those of aluminium and chromium, but which have not yet attained any commercial importance.

We may now pass on to notice very briefly what is the oldest and, perhaps, still the most important of tanning methods—the vegetable tanning process. In principle this is practically the same as was used by our forefathers, though in detail it has undergone great modifications, the most important of which is the use of much more concentrated solutions produced either from exotic materials naturally stronger than proverbial oak-bark, or concentrated artificially by the use of the vacuum pan. A good instance of the latter is the very important "oak-wood extract." Oak-wood naturally is only about a quarter as strong as oak-bark, and can hardly be used for direct tanning, though large quantities of branch-wood, sawdust, and other waste are available. By the concentration of weak liquors, syrupy liquids containing 25 to 30 per cent. of tanning matters are produced, which are suitable for modern requirements. The sources of such extracts were principally Southern Austria and Northern Italy, and their disappearance during the war, together with that of the Turkish acorn-cups, known as "valonia," has led to an absolute famine of tanning materials, and contributed much to the scarcity and enhanced prices of leather.

In principle the process consists in soaking the prepared hides in solutions of the class of organic substances, known as "tannins," which differ considerably in chemical constitution, but have the common characteristics of precipitating gelatine and converting skin into leather, and are very widely distributed in barks, woods, leaves, and even roots. Whether the precipitation of gelatine and the analogous action on skin are strictly chemical or physical processes has been much discussed, but the facts are as follows. Both tannins and gelatine are distinctly colloid in character—that is, they have either very large molecules, or these molecules exist in groups in the liquid, as colloid and not true molecular solutions. These particles are electrically negatively charged, while gelatine and skin fibres in slightly acid solution are positive. When, therefore, the two are brought together they attract each other by their opposite charges, unite, neutralise, and precipitate. The mechanism of the combination is not different from that of positively and negatively charged ions, such as sodium and chlorine, but it deals with whole molecules or particles instead of ions, and it seems a matter of taste whether we call it chemical or physical. In faintly alkaline solution the skin or gelatine particles, from their amphoteric nature, take negative instead of positive charges, and in this condition are not tanned or precipitated by tannins. Hence in tanning, faint acidity of the liquors is essential, though what is the *optimum* acidity has not been fully determined, and must depend upon the character of the leather desired. Acidity causes swelling of the fibres which leads to hardness and stiffness, and thus for the softest and most flexible leathers the smallest possible swelling is required, while for sole much more is desirable. The degree of swelling is also affected by the neutral salts, as was earlier explained, so that the solution of the problem does not merely depend on acid-concentration. The minimum swelling is obtained slightly on the alkaline side of absolute neutrality, on which tannage would not be practicable.

While what may be called the first stage of tanning is purely chemical in the sense which has been explained, there comes, at least with the heavier leathers, a stage in which adsorption or surface-attraction predominates, and when a sort of chemical equilibrium has been attained, the fixation of the less soluble and more colloid constituents of the liquors on the surface and between the fibres still goes on and adds to the weight and solidity of the leather, and no doubt in the old and slow methods of tanning earlier in vogue this played a larger part than it now does. The matters so deposited are principally ellagic acid (bloom) and the anhydrides or oxidation-products of tannins, which are only slightly soluble in water, and easily separated from it.

Besides the quickening due to the use of more concentrated liquors, many attempts have been made to quicken the slow diffusion into the leather of the colloid and slowly diffusible tannins. The most successful of these has been by the mechanical movement and bending of the hides in rotating drums and other similar devices, which cause a sort of pumping action between the fibres, and heavy leathers can be

tanned apparently well in three or four days which would take as many months by the old diffusion process. It is difficult to say to what extent such processes are in use, as drum-tanned leathers have not a very good reputation, and tanners are not anxious to advertise the fact that they make them, but there is no doubt that large quantities of leather are wholly or partially so made, and within limits this is very justifiable, especially under war conditions.

Much has been talked from time to time of the use of electricity for quickening tanning. Colloid particles are moved by electric currents by the effect called "electrophoresis," and may so be forced into or through leather, and it is pretty certain that tanning can be hastened in this way, though whether to an extent and at a cost commercially profitable may still be an open question.

The "vacuum" process is an interesting method of quickening tanning, and is being used on a considerable scale by the limited company which owns the patent. The hides are suspended in vats, which can be exhausted to so high a vacuum that the liquors actually boil in and round the hides at a temperature not exceeding 75 to 80° Fahr., and the interchange of liquor so caused considerably increases the rapidity of tanning. The process has little in common with the vacuum processes used in forcing preservatives into wood, which in the dry state is filled with air; this expands and escapes under reduced pressure, while hides contain only water, which does not practically expand unless it boils, and hence low vacua are useless.

There are many processes in important commercial use which are combinations of mineral with vegetable tannages, and especially with chrome and alumina, which contain nothing new in general principle, and of which time does not allow description, though the fact is interesting that hide saturated with the one is still capable of absorbing the other, probably because of its amphoteric nature. One of the latest of these is "pyrotan," a combined alumina and vegetable tannage, in which the alumina is precipitated and fixed in insoluble form by sodium pyrophosphate.

A more interesting study is the action of aldehydes, and especially of formaldehyde, in leather-making. Formaldehyde is a volatile liquid which evaporates without residue, so that it cannot well deposit anything on the fibre, according to Knapp's theory. It forms polymerised or conjugated compounds with many substances, and among others with hide-fibre, which it renders insoluble in boiling water. Applied to hide in the swollen condition, it fixes it in that state, and therefore has been applied as a preparation for hides for rapid vegetable sole-leather tannage. Payne and Pullman patented a method (1898) for its use as a tanning agent in conjunction with sodium, carbonate, and other alkalies, and very successfully made both imitation buff-leathers for military accoutrements, and soft washable leathers for gloves. Professor Meunier (1912), however, has shown that it is not the alkalinity, but the dehydrating effect of the sodium carbonate, which is important, and that other dehydrating salts, such as sodium thiosulphate, can be used with equal effect. A strong solution of potassium carbonate alone will produce a perfectly supple white leather, which, of course, becomes pelty again by washing, and dries hard and horny. If, however, three parts of neutral formol be added to the alkaline solution, a similar white leather is produced, which perfectly resists washing. The effect of formol is therefore merely to fix the skin-fibre in the condition, swollen or dehydrated, in which it finds it. Formaldehyde can be used in this way in connection with vegetable, chrome, or alumina tannages.

Interesting tannages which may be related to aldehyde tannages are those produced by the action of oils, as in washleather, buff, and buckskin, and the best modes of fur-dressing. Common washleather ("chamois," or "shammy" leather) is a typical example, and is produced by fulling the flesh sides of sheepskins in "stocks" while adding fish- or whale-oil until the pelts are thoroughly saturated. They are then packed in boxes, where they heat rapidly by oxidation, so that they must be taken out and aired at intervals, not merely to provide fresh air, but to prevent dangerous overheating. The skins turn deep yellow, and are converted into leather by the oxidising oil, and large quantities of pungent acrolein, or acryl-aldehyde (very lachrymatory), from the dehydration of the glycerine are given off. When heating ceases, the skins are wrung or pressed to remove surplus oil, which is valuable for stuffing other sorts of leather (degras, moêllon, sod-oil), and after washing with soda or potash solution, and fluffing on an emery wheel, are ready for use. Knapp's simple explanation that the process is an isolating and coating of the fibres with oxidised oil products is negatived by the fact that all the

latter are saponified, and washed out by alkaline solutions, and also the plausible view that the acryl-aldehyde is the real leathering agent, since Wood has shown that equally good leathers can be made with the fatty acids of oils from which the glycerine has been removed. This does not, however, entirely negative the aldehyde explanation, since only "drying" or unsaturated oils can be used, and their acids frequently split at an unsaturated bond, giving aldehydes as products. Marine oils are invariably used in practice, but Fahrion has shown that linseed and other unsaturated vegetable oils will also produce the effect, and the very tough and beautifully white Japanese leather, used for brace tabs and the like, is made with rape oil. Fahrion shows that oils must have at least two double linkages to produce this effect (marine oils have three or four), and Meunier points out that this produces a quinonoid structure by oxidation.

Marine oils are largely used in currying vegetable tanned leathers, and if the latter are not fully tanned, produce a sort of supplementary oil tannage very advantageous to the quality.

In addition to the present methods of making leathers there are many others possible, and some which have been commercially used on a limited scale. Meunier has shown that leather may be produced by the action of bromine, probably by forming insoluble bromamines, and that the various quinones are quite practical tanning agents, being partially converted into hydroquinones and giving good brownish-coloured leathers. He attributes the action of vegetable tans to the quinonoid bodies already present or formed by oxidation, and has shown that the power of most phenols to insolubilise gelatine is dependent on quinones formed by oxidation. A good many "synthetic tannins" have been patented, bearing no close chemical relations to the natural tannins, but having pronounced tanning properties. Much the most important of these are Stiasny's "Syntans," one of them, "Neradol" being now largely manufactured in this country by Government license under various names, and used in conjunction with other materials for plumping and bleaching, as alone it gives an almost white, but somewhat empty leather. It is produced by condensing sulphonated cresols with formaldehyde. Zacharias long ago showed that many aniline dyes, and especially the methyl violets, will also produce leather if used in sufficient quantities.

Distinguished from these are various colloid precipitates which, drummed into the skin, convert it into leather by coating and separating the fibres according to the old Knapp theory. In the two-bath chrome process the sulphur precipitated on the fibre considerably increases its softness and fulness, and by treatment with acids and sulphur-yielding compounds without the chrome, purely sulphur leathers may be made. Freshly precipitated alumina has considerable tanning properties, and phosphate leathers may be made by precipitating phosphate of lime in the skin, while most metals giving basic and colloid salts, as for instance titanium, may be used in producing leather. A process for tanning with colloidal silicic acid has been patented by Mr. A. T. Hough (English Patent No. 17,137 of 1915), which seems to give results of considerable practical value.

Probably enough has been said to show that no single theory can account for all the various ways in which leather can be made, and that there is no limit to the varieties which may be produced.

INDUSTRIES AFTER THE WAR.

IV.—TEXTILES (*continued from p. 755*).

Silk.

The manufacture of silk goods on a commercial scale in these isles appears to have begun with the immigration of Flemish and Huguenot weavers in the sixteenth and seventeenth centuries. From the first the trade was a protected one. Without protection it would probably never have taken root on this side of the Channel at all, as it had to face the competition of countries where silk industries had been in existence for hundreds of years and had attained a high degree of efficiency. Comparative prosperity prevailed until the adoption of Free Trade and the ratification of the Cobden Treaty. As compared with the United States—now the largest purchaser of raw silk in the world—France, Germany, Italy and Switzerland, the English industry is not in the front rank of our industrial activities. Statistics prepared by Sir Frank Warner, K.B.E., and quoted in the report of the Board of Trade Committee, show that in 1911 the entire production of silk amounted to 24,613,000 kilos, our share being under 630,000 kilos. America has gone ahead immensely in recent years, having increased her consumption from two million kilos in 1892 to twelve million kilos in 1913. In normal times approximately 66 per cent. of the raw material is supplied by Japan and China and 19 per cent. by Italy and France. A generation or so ago Japan only produced some seven thousand bales, and the quality was indifferent; her exports of "superlative silk" last year (to say nothing of her home consumption) were expected to total 150,000 bales,

valued at thirty million pounds sterling. Germany, though ranking second among the consuming countries in Europe, does not produce any raw silk whatever, and Austria-Hungary's production has been less than half her consumption. Turkey is the sole enemy country with a considerable surplus. Within the past fifty years there has been a serious decrease in the Indian supplies, largely in consequence of the deterioration of the Bengal cocoon and inferior reeling; nevertheless, the prospects in India are described in the report under notice as promising. Under qualified supervision the quality would be greatly improved. Kashmiri silk, grown at an altitude of 6,000 ft., compares favourably with the Japanese varieties. There is little doubt, the Committee says, that the foothills of the Himalayas lying within the United Provinces, the Punjab, Bhutan, Sikhim and Nepaul, are as well adapted to sericulture as those in Kashmir, where it is a State monopoly. The population of the districts referred to is almost equal to that of Japan and the area is much larger. "The main desideratum is a spirit of enterprise similar to that shown by the Government of Kashmir, and it would appear that efforts should be made by the Indian Government to encourage the development of sericulture within this large area." In the past two years operations on a limited but definite basis have taken place in the Native State of Patiala, "under the supervision of a native graduate of the Montpelier School in France." The first parcels of raw silk reaching this country from Patiala are described by experts as equal to the best Kashmir. With the exception of a small quantity from Kashmir, Indian waste is not used by English spinners because it is "mixed with impurities." In this section of its report the Committee makes the following recommendation: "Although the supply of raw silk and silk waste keeps pace with the continually increasing world's consumption, we recommend the development, under efficient direction, of sericulture in India and its stimulation and encouragement in those parts of the Empire where climatic and labour conditions are favourable." With the adoption of scientific methods, there are possibilities in the African colonies, especially Uganda and the highlands of Rhodesia.

Considerably more than thirty-six million pounds of "silk waste," from which schappe, spun yarns, sewings and noil yarns are made, is produced for consumption in Europe and America.

The British silk output in 1907—there are no later authentic figures—was of the value of £5,236,000, made up as follows: Piece goods, £2,262,000; spun silk yarns (including sewing silks), £1,250,000; lace, net trimmings, etc., £879,000; thrown silk, £394,000; and miscellaneous articles, £451,000. Fifty-three per cent. of the whole was disposed of in home markets. The Committee divides the trade into various groups, viz.:—

(a) *Spun Yarns and Sewing Silks.*—This is the most important single branch of the industry in this country. Of a total of 32,000 operatives employed in the whole industry about 10,000 are engaged in the spinning of yarns from waste silk. English spun yarns are said to be the best in the world, and are exported to Calais and Malta for lace-making, and in large quantities to the United States. The industry is well organised, fairly prosperous, and is mainly established in Yorkshire and the adjacent counties of Lancashire, Cheshire, and Staffordshire. The principal centres are Brighouse, Bradford, Leek, Congleton, Macclesfield, and Taunton. During the past few years spinners have been well employed. Competition in the past has been met with from Switzerland, France and Italy, but since the year 1912 there has been a considerable increase in the imports of Japanese spun yarns. British spinners regard this competition as a serious menace for the future.

(b) *Tie Silks, Cravats, Mufflers, Handkerchiefs.*—The manufacture of high-grade articles for men's wear has for long been one of the strongest branches of the silk industry. British fashions still lead the world in these articles, and although the industry has not increased to any appreciable extent, our manufacturers appear to be holding their own in the best classes of goods where design and quality are essential features and price is not of great importance. In the cheaper articles, however, Germany and Austria were very strong competitors before the war. Macclesfield is the centre of this industry, which is also carried on in the Glasgow district, Norwich, and the West Riding of Yorkshire.

(c) *Mourning Crêpe and Crêpe de Chine.*—Mourning *crêpe* is almost exclusively a British production, and is manufactured in the eastern counties of England. The principal markets are France, South America, and the United States. British manufacturers employ a special process by which the *crêpe* is waterproofed and does not lose its appearance when exposed to moisture. The trade declined considerably when mourning *crêpe* went out of fashion in this country, but, in France and other markets where it is still fashionable, the veil and important parts of dresses are of British manufacture.

A large quantity of *crêpe de Chine* is manufactured at Braintree, Norwich, and Yarmouth, but severe competition is now experienced from Japan.

(d) *Dress Silks.*—This is probably the weakest branch of the British silk industry, and it is the one in which foreign manufacturers practically hold the field. A small quantity of "net silk" dress goods are made in Macclesfield, in Lancashire, and in Yorkshire, and of mixed goods in the eastern counties. In Bradford and its neighbourhood, spun silk and mixed piece goods are made successfully. The great firm of Listers produces "pile" fabrics, which are known all over the world.

(e) *Lace, Net and Hosiery.*—These special articles are manufactured at Nottingham, Derby, Leicester, and in Devon and Somerset. The competition

met with is almost entirely from French millinery tulle. This industry is dealt with in the lace section of the report.

(f) *Narrow Goods, Braids, Ribbons, Hatbands.*—These are manufactured at Leek in Staffordshire, and to a less and decreasing extent at Coventry. Hat galloons are also made at Denton, furniture trimmings of the best quality in London, and the cheaper kinds at Leek, Macclesfield, Derby, and Coventry.

(g) *Furniture Silks and Specialities.*—Braintree is the chief centre for the manufacture of the richest brocades for court gowns, of figured velvets, and of other fine silk fabrics for decoration and upholstery. A considerable quantity of cheaper furnishing fabrics are manufactured at Bradford and Halifax mostly from spun silk mixed with cotton and wool.

(h) *Umbrella Silks.*—The finest umbrella silks are still made at Sudbury in Suffolk.

It will be seen that our manufacturers mainly devote themselves to turning out "specialities," in which they are able to hold their own against all their competitors abroad. The trade in the staple lines of plain and fancy dress goods is in the hands of four Continental countries—France, Italy, Germany and Switzerland—as well as Japan and China. Unlike the cotton industry, there is in the United Kingdom no large "plain" silk trade to permit of a very large outturn and corresponding enterprise on the part of manufacturers.

It is estimated that the wholesale value of silk goods annually consumed by this nation is £16,000,000, of which all but 20 per cent. is imported. The following table gives particulars about the imports in 1913:—

Country whence Imported.	Raw Silk.	Thrown Silk.	Spun Silk Yarn.	Silk manufactures and manufactures of Silk mixed with other materials if known as Silks.	Total.
European—	£	£	£	£	£
Allies	211,909	241,639	62,703	7,127,742	7,643,993
Enemies	26,901	207,286	19,411	2,515,701	2,769,299
Neutrals	—	15,827	114,633	3,266,570	3,397,030
Extra European—					
India	15,140	—	—	12,223	27,363
China	287,851	—	—	221,735	509,586
Japan	74,970	—	19,963	1,193,813	1,288,746
Other Countries	2,656	244	570	95,321	98,791
Total	619,427	464,996	217,280	14,433,105	*15,734,808

* Of this total nearly £2,000,000 was subsequently re-exported.

Japanese competition, as mentioned above, is regarded by our silk spinners as a very serious menace. The Committee was informed that the Japanese can sell the lower counts of spun silk yarns at less than the bare cost of production here. On labour cost alone the Japanese have an advantage of 1*s.* to 3*s.* per lb. Witnesses expressed the fear that unless an import duty is imposed on these yarns equivalent to the difference in the cost of labour, the British spinning industry will really be threatened. Imports consist of (1) high-grade plain and figured dress goods, ribbons and laces, and rich furniture silks, mainly coming from France; (2) plain and figured goods for men's and women's wear, such as taffetas, satins, coat-linings, tie silks, brocades, ribbons and trimmings of no particular merit, all heavily weighted in the dye and low in price, the chief sources of supply being Germany, Switzerland and Italy; (3) Eastern piece goods—Shantungs, Corahs, Pongees and Japanese Habutae.

The unsatisfactory position of the silk industry in this country is not due by any means to inferiority in quality. Actually, the productions of our mills are, on the whole, superior in design and colour to any foreign article—the French, of course, excepted. They also contain less adulteration and wear better. "The success of most foreign imports," says the Committee, "is due to their relatively low price. Germany, Switzerland and Italy have large silk industries, which are able to produce on a large scale. All of them 'dump' their surplus goods upon the free and open market of Great Britain." The general contention of witnesses was that the British industry cannot become a large one and manufacture on a large scale "unless it has some assistance from a tariff in its own market." From the replies to a *questionnaire* issued by the Silk Association, as well as from the oral evidence, it is clear, says the Committee, that the trade is almost unanimously in favour of the imposition of a tariff on imported piece and made-up goods as follows: Allies, 15 per cent. *ad valorem*; neutrals, 29 per cent. to 25 per cent. subject to reciprocal arrangements; undyed goods of Chinese and Japanese manufacture, 12 per cent. to 16 per cent. *ad valorem*; enemy countries, 40 per cent. With regard to thrown silk and spun silk yarns received from Allies, opinions are divided between free entry and a small duty.

Of our silk manufactures exported in 1913, valued at two millions sterling, 68 per cent. went to foreign countries. Our best pre-war

market for spun silk yarn was America—£227,000, out of £391,000. The value of all classes of our silk goods taken by the British possessions was £659,000, the figures being:—

Countries.	Spun Silk Yarn.	Broad Stuffs.	Lace.	Other Manufactures.	Total.
	Thousand £	Thousand £	Thousand £	Thousand £	Thousand £
Australia	17	65	1	77	160
New Zealand	—	6	—	20	26
Canada	17	121	3	74	215
South Africa	—	9	—	11	20
British India	14	62	—	18	94
Other	28	73	3	40	144
Total British Possessions	76	336	7	240	659

The Japanese have not only become keen competitors in our home market for two-fold weaving yarns, but have also captured a large portion of the trade which was formerly done by ourselves in India.

The finest silks are still woven in hand-looms, this being done generally by skilled workers in their own homes. On the other hand, there has been a great decline in this interesting domestic industry during the past two decades, so much so that at present the proportion of our hand-looms to power-looms is smaller than anywhere else in the world, excluding the United States. Lyons still possesses 15,000 hand-looms for brocades and delicate silk fabrics. Not one thousand are now used in this country.

Whatever may have been the case in the past, present-day silk manufacturers are well grounded in the technique of their craft. It is, we are told, a rare thing to find a working member of any firm who has not been through a course of practical instruction at Macclesfield, or Bradford, or Manchester. Some have been trained also at Lyons or Crefeld. Art and technical schools are established at the principal silk centres, but there is urgent need of an institution fully equipped with the more modern types of machinery, and in all respects equal to the best institutions of the kind on the Continent.

(To be continued.)

INDIAN INDUSTRIES COMMISSION.

The Indian Industries Commission have issued their report. According to a summary telegraphed from India, the administrative proposals include the creation of Imperial and Provincial Departments of Industries and of Imperial Industrial Service. The Imperial Department would be in charge of a member of the Viceregal Council, assisted by a Board of three members entitled the Indian Industries Board, and be responsible for the industrial policy of the Government and the inauguration and carrying out of a uniform programme of industrial development throughout the country. A large staff of officers would be employed, whose qualifications would primarily depend on a knowledge of mechanical engineering, and the formation of an Imperial Industrial Service is suggested.

Proposals are made for the better exploitation of the forests and fisheries. It is vital for the Government to ensure the establishment in India of those industries whose absence exposes us to grave danger in the event of war. The report advocates the introduction of modern methods of agriculture, and in particular of labour-saving machinery. The Commission recommends a special survey of the coal position in India. Attention should be directed to more economical methods of using wood fuel and new materials for industrial alcohol.

With regard to artisans, the Commission recommends universal primary education, and education of a technical kind is also required. For cottage industries the Commission proposes education in industrial schools, administered by headmasters with practical knowledge of the industries taught. In the case of organised industries mechanical engineering is taken as a typical instance, and the proposal includes the establishment of a system of organised apprenticeship for a period of four or five years. The Commission places better housing in the forefront of its recommendations to raise the standard of comfort of the Indian artisan. Special proposals are made for commercial and mining education, and the future establishment of two Imperial colleges is adumbrated, one for the highest grade of engineering and the other for metallurgy.

The Commission is disposed to favour the establishment of an industrial bank or banks, but considers that the appointment of an expert committee is necessary to deal with this subject, and asks the Government to take action at an early date. As an interim measure, a scheme is propounded for the provision of current finance to middle-class industrialists by which the banks would open cash credits in favour of applicants approved by the Department of Industries on the guarantee of Government.

The recurring cost of the proposals is estimated at eighty-six lakhs of rupees (£573,000), and they involve capital expenditure of 150 lakhs, mainly

on educational institutions, and a further capital outlay of sixty-six lakhs is anticipated for future developments. The Commission consider that this expenditure may be worked up to at the end of a period of seven years.

SIR GEORGE BIRDWOOD MEMORIAL.

The following appeal has been issued:—

Many friends of the late Sir George Birdwood have expressed a desire that his memory should be perpetuated in a tangible form.

It is felt that no more fitting memorial could be devised primarily than a "George Birdwood Lecture," to be delivered annually in connection with the Indian Section of the Royal Society of Arts, with which he was so closely associated for upwards of forty years, and in whose work he continued to take an active part almost to the very day of his death.

It is intended that the lecture shall be upon subjects relating to the art, literature, and social phenomena of India, the honorarium to consist of the Society's gold medal (with suitable inscription) or the equivalent in money, at the option of the lecturer.

The Council of the Royal Society of Arts cordially approve of the idea, and will be glad to administer the funds collected in accordance with the wishes of the donors.

Subscriptions may be paid to Mr. T. J. Bennett, C.I.E. (Honorary Treasurer), Royal Society of Arts, John Street, Adelphi, London, W.C. (2)

F. W. Duke (*Chairman*), A. Henry McMahon,

Valentine Chirol, N. N. Wadia,
S. Digby (*Hon. Secretary*).

TOBACCO IN HONDURAS.

An account is given in *Commerce Reports* (Washington) of Honduras tobacco, which has always enjoyed a pre-eminent position in the estimation of Central American tobacco smokers, so much so that native tobaccos of the neighbouring Republics are often put on the market under the name of "Tabaco de Honduras," in order to obtain higher prices. It is commercially known as "Copan tobacco," because the best quality and largest quantities are produced in the Department of Copan, which borders on both the Guatemalan and Salvadoran frontiers. It is also produced in commercial quantities in the Departments of Ocotepeque, Gracias, Santa Barbara, and El Paraiso, the capitals of the respective Departments being the marketing centres. The estimated average annual production of each district is as follows: Paraiso, 7,500 lb.; Santa Barbara 250,000 lb.; Gracias, 50,000 lb.; Ocotepeque, 410,000 lb.; and Copan, 1,000,000 lb.

Planting, Harvesting, and Curing.—Tobacco is planted during October—that is, from two to four weeks before the close of the rainy season—so that the young plants have sufficient time to take root before the long dry season sets in. The seeds are planted in nurseries during July, and the young sets transplanted about four months later. One pound of seed should produce approximately 20,000 plants, and growers place about 2,250 plants to the acre.

The leaves are ready for gathering between February and April, and the custom is to start harvesting as soon as the plant has fully developed. This is sometimes determined by the appearance of yellow tints in the leaves or when the leaves show signs of brittleness on being doubled or bent. The stock is cut whole a little above the roots, and the seed is obtained later from the suckers that sprout from the remaining lower part of the stem. The stocks are then hung out, head down, in the open air and exposed to the sun. If any are harvested in the rainy season (which is rare) they are dried in the shade. After being dried in the sun for fifteen or twenty days, the stocks are pressed for three days, and the leaves are then separated from the stems and sorted into three grades, according to size. They are then tied in bundles of 1 lb. each—the stems being utilised for fastening—and are alternately pressed and sunned until the veins are thoroughly dried. Owing to negligence and the varying judgments of different farmers, the resulting product is not always uniform, which sometimes results in obtaining lower prices. Dried leaves average from 9 to 20 inches in length, and a well-cultivated acre should yield from 400 to 650 lb.

Both strong, mild, dark, and light tobaccos are produced, these properties depending largely upon the nature of the soil and, to a somewhat lesser extent, upon the amount of rainfall and the time and method chosen for cutting and curing. If the plants are permitted to ripen thoroughly, the leaves will be rather dark in colour, whereas if cut earlier a lighter shade will be obtained. A poor, sandy soil is said to produce a mild tobacco, and a rich clay soil a somewhat stronger plant. In seasons of copious rainfall it is noticed that the leaves are invariably of a dark hue.

Cost of Production.—It costs from 8 to 12 cents United States currency to raise a pound of tobacco in Honduras, and the market price ranges from 15 to 25 cents, according to the class and quality It is supposed that most of the tobacco cultivated in Honduras was originally derived from Cuban seed, and the more progressive growers still continue to import Cuban, Jamaican, Porto Rican, and American seed. When ready for market Honduran tobacco closely resembles that grown in North Carolina and Virginia. It burns well and has a pleasant aroma, and connoisseurs state that its failure to achieve just recognition of its

worth is due solely to the primitive and unscientific methods employed in its harvesting and curing.

Methods of Packing—Export Trade in Tobacco.—Tobacco is packed for shipment in bales of 100 lb. each, which are well wrapped in several layers of banana leaves and tightly tied with strong banana fibre. Although apparently crude, this method of packing is considered the most practical, combining as it does the qualities of lightness and cheapness.

As the tobacco fields of Honduras are in closer proximity to the railroads and seaports of Salvador and Guatemala than to those of Honduras, nearly all the crop is strapped on the backs of native Indian runners or mules, and carried over the frontier trails to the neighbouring Republics. These caravans pass the border at remote hamlets, where no custom houses are established, so that statistics showing the volume of this trade are not available. However, it is well known that practically all of the high-grade cigars and cigarettes manufactured in Central America are either of pure Honduran tobacco or contain a large admixture of it. The amount and value of tobacco exports through the seaports of Honduras for the years 1915 and 1916 respectively were 56,800 lb., worth $6,810, and 89,025 lb., worth $19,610.

Honduras tobacco, after being manufactured into cigars and cigarettes in Guatemala and Salvador, is exported in considerable quantities to South America, particularly Peru, the Caribbean countries, and Europe. The volume of this business amounts to many thousands of dollars annually.

Efforts made to expand industry and markets.—Of recent years the Honduras Government has taken measures to foster the industry, and aside from maintaining several schools, where young natives are taught to cultivate and cure the crop scientifically, steps are being taken to improve the quality of the plants, and to find new outlets for the constantly increasing production. The Government recently sent several youths to the tobacco districts of Cuba, where they were able to study the up-to-date methods employed there in the various branches of the industry.

Tobacco is principally used in Central America for cigars and cigarettes; pipe-smoking and chewing have not been introduced among the natives, although nearly all of them, including women, smoke. Among the labouring classes the women of nearly every household prepare the cigars and cigarettes for the family needs. During the fiscal year 1914-15, $7,480 worth of cigarette paper was imported, the greater part of this supply coming from Spain and small shipments from the United States and Germany.

Up to the present no attempts have been made to manufacture high-grade cigars or cigarettes on a large scale, although, with an abundance of raw material and cheap labour, it would seem to warrant a careful investigation. Nearly every man and woman of the labouring class understands the rudiments of cigar-making, although none of them are particularly expert at it. However, they could soon be trained to turn out as good cigars as are manufactured in Cuba. An almost unlimited supply of this labour could be obtained at from 25 to 50 cents per day. Cigar factories in Guatemala utilise native labour, and their products (Honduras tobacco with Sumatra wrappers) are said to compare favourably with those of many factories in Cuba, Porto Rico, and the Philippines.

In addition to supplying the demand for good cigars in Honduras itself, a profitable market could be worked up among the other Central American Republics.

ENGINEERING NOTES.

The Cost of Railway Electrification.—Data now available covering the conversion from steam to electricity of several railway systems in the United States, show that the cost of conversion in the case of lines with a reasonable amount of traffic is amply justified from the financial standpoint. The Butte Anaconda and Pacific Railway, which was electrified in 1913 at an initial cost of £248,126, showed a total net saving per year over steam operation of £49,758, exceeding 20 per cent. upon the entire cost of the electrification. In addition to this definite money saving, the railway, according to the report, secured a greatly increased capacity and a much improved service, and these facts having been well acknowledged, the indications are that the Federal Government will take steps to conserve the existing supply of coal and fuel oil by assisting to finance such electrification as competent engineering authorities are able to show will make the greatest saving in fuel. In order to establish a definite ratio of comparisons between the efficiency of the steam locomotive and the electric system, data have been compiled showing that, as an average figure, 7 lb. of coal on the tender of a steam locomotive on the electric system is equivalent to a kilowatt-hour of electricity in the alternating current switch-board of the power-house. A kilowatt-hour of electrical energy can be produced in a modern plant with 2½ lb. of coal, the deduction therefore being that it requires 7 lb. of good coal in a locomotive fire-box to haul the same amount of net tonnage as could be dealt with by an electric locomotive burning 2½ lb. of coal in an up-to-date power-house. This information is taken from the *Railway Gazetté* of September 6th.

Steel Production of Manganese.—A leading article in the *Indian and Eastern Engineer* of July says that the production of a very considerable percentage of the world's output of steel is dependent on the supply of manganese ore, and as now the Russian supply is cut off, India is the largest producer. For the production, let us say, of 5,000,000 tons of steel requiring 17 lb. of 80 per cent. ferro-manganese per ton, at least 80,000 tons of the alloy would be required, necessitating the mining, transportation, and smelting of more than

200,000 tons of manganese ore. During the last peace years the world's output of manganese ore ranged from 2,000,000 to 2,250,000 tons, of which nearly one-half came from Russia. India, the second largest producer, had a production of 450,000 tons during 1915, and 645,000 tons during 1916; the next largest output is that of Brazil, which is less than one-third that of India. It follows that, however large the Indian output may be, there is a ready market for it, as all other countries do not in the aggregate produce one-third that of India. Russia exported large quantities of manganese ore to Great Britain—during the last peace year 241,800 tons — whilst the United States depended on Great Britain for supplies of ferro-manganese. Dwindling arrivals from this source have caused acute difficulties to American steel manufacturers. About 30,000 tons per month are required by them. No satisfactory substitute is known for ferro-manganese for the particular purpose for which it is used in steel-making, and in practice only an alloy with a high percentage of manganese is efficient.

The Reclamation of Scrap Iron.—The *Railway Gazette* of September 13th says that the iron and steel mills of the United States are greatly in need of scrap iron, the demand for this material far exceeding the supply. The railways have always been one of the largest sources of supply for scrap iron and steel, and the prices now being paid for such materials are sufficiently high to warrant special efforts in the collection of scrap. Apart from this consideration, it is felt that the railways should do their best to make up the deficiency for patriotic reasons. It has been calculated that if the whole of the iron and steel scrap in the country were marketed there would be no shortage of steel, but this can only be accomplished by very great effort. The railways can not only be of great help in collecting and marketing their own scrap, but they can do much by urging others with whom they come in contact to do the same, and by helping to promote and encourage "Sell Your Scrap" campaigns in the different communities which they serve.

New American Automatic Train-stop. — This device, invented by Mr. Schweyer, was exhibited in operation before a large company of railway officials and others on the Philadelphia and Reading Railway on Sunday, June 23rd. In this system an electric current (alternating) controlling air-brake valves on the locomotive is run through a choke coil, which is so fixed on the engine frame as to move in line with a "track armature" 30 in. long, fastened on the sleepers 13 in. outside the gauge line. The choke coil and the track armature are $2\frac{1}{4}$ in. apart, and there is nothing movable in either of them. On the passage of a train the armature weakens the current on the engine, and thus causes the setting of the brakes. A roadside battery, in connection with a short section of insulated track and an insulated truck of the locomotive, is arranged so as to neutralise this stop-operation, as may be desired, whenever the track ahead is clear. The tests were made under all three of the normal conditions—clear, caution and stop. The caution indication was arranged to reduce speed but not to stop the train, and the stop indication was arranged to apply the brakes in emergency. In the caution test, a service application of 15 lb. reduction was made, which resulted in a reduction of speed from approximately thirty-five miles an hour to about twenty miles an hour before the next ramp (track armature) was reached. This test was not considered satisfactory and it was repeated, with a service application of 25 lb. reduction. This application reduced the speed gradually from about thirty-five miles an hour until the train reached the next ramp, when it was brought to a stop in less than 100 ft. The test for a full stop was made at the entrance of the signal section, and there was no preliminary caution signal, with its ramp to give the customary reduction of speed. The speed over this ramp was approximately thirty-five miles an hour, and the train was brought to a stop in 700 ft. with the throttle open. After the regular tests were completed a number of runs were made to test the electro-magnetic fixture which is placed between the rails, and is designed for use on an electrified railway in place of the insulated track section. These tests, like the others, fully met expectations and requirements.

Electric Steel Production.—A recent development in the metallurgical industry which merits comment is the very great increase in the production of steel made by electric furnaces. According to Professor Carpenter, F.R.S., of the Imperial College of Science and Technology, previous to the war the output was so small that it did not figure in any returns of steel production. Nevertheless, in 1917 no less than 110,000 tons of electric steel were made, of which 90,000 tons were in the form of ingots and 20,000 tons in castings. At the present time upwards of fifty furnaces are at work in the various Sheffield works.

Aluminium and its Alloys.—Dr. Rosenhain, in an address on this subject at the British Science Exhibition, said that aluminium alloy was not a German monopoly. A Zeppelin framework had a tensile strength of 25 tons to the square inch, but this is not so good as the combination of lightness with high strength that could be produced in this country. Comparing steel having a tensile strength of 28 tons to the square inch, with pure aluminium of 7 tons strength to the square inch, he said that the length of a vertical bar of steel that could just carry its own weight would be 19,000 ft., and of aluminium 14,000 ft. But with alloy the length of the aluminium bar would be extended to 50,000 ft. In large structures like bridges the weight of the structure was so great that the weight of a train was almost negligible, but the point came where

the span could just carry itself; and, in comparison with steel, the light alloys of aluminium could increase the limiting span threefold. There was great expenditure of energy in starting and stopping electric trains, and if the heavy steel parts of locomotives could be replaced by light alloys there would be quicker starting and stopping, and an important saving.

OBITUARY.

Sir James William Restler, K.B.E., M.Inst. C.E., M.I.Mech.E.—Sir James Restler died suddenly at his residence in Queen's Gate on the 4th inst. Born in 1851 he was educated privately, and at King's College. In 1883 he was appointed Chief Engineer to the Southwark and Vauxhall Water Company, and on the acquisition of the Water Companies by the Metropolitan Water Board in 1904 he passed into the service of the Board. The works constructed under his supervision cost over £2,500,000, and included engines capable of raising 140,000,000 gallons of water per day, reservoirs to hold 1,800,000,000 gallons, very large filter-beds, five tunnels under the Thames, and a number of deep wells. He was consulting engineer to several private and local water enterprises, director of various companies, and chairman of the Metropolitan Munitions Committee. In recognition of his public services he was knighted last June.

He had been a member of the Royal Society of Arts since 1892.

GENERAL NOTES.

Enemy Aircraft Exhibition.—The exhibition of enemy aircraft at the Agricultural Hall, Islington, will be opened to the public on the 15th inst. Numerous types of machines will be on view, which will show not only their external features, but also their actual construction. Amongst other famous aircraft there will be on exhibition the Gotha, Friedrichshafen and A.E.G. bombing planes; the Halberstadt, L.V.G., D.F.W., Rumpler and Hannoveraner two-seater; the A.E.G. armoured trench fighter two-seater; and the Fokker, Pfalz and Albatross scouts. There will also be a complete array of engines and accessories, including wireless gear, machine-guns, bomb-sights, electrically-heated clothing, and innumerable aviation instruments.

British Industries Fair, 1919. — The 1919 British Industries Fair, organised by the Board of Trade, will be held, as last year, in the Pennington Street warehouse of the London Docks from February 24th to March 7th. In order that there may be no possible interference with the production of munitions, it will again be confined to the same trades as before, viz., glass and pottery; paper, printing and stationery; fancy goods; toys. The right to exhibit will be confined to British manufacturers.

Water-power in Tasmania.—The wonderful possibilities of Tasmania for the development of water-power are commented on in *Power*. The island possesses just in its centre, on a high elevation, a lake sufficiently large to provide its industries with all the electrical power that may be needed for some time to come. The basis of the whole system is the Great Lake. With a catchment area of 216 square miles, and a water area of 50 square miles, it forms an ideal foundation for a great hydro-electric enterprise. A dam that has been constructed on the southern outlet of the lake provides for an even depth of 11 feet above sill level, and experience has proved that this will be sufficient to guarantee a regular flow of water. Experiments made during the first year of operation have shown that during a year of normal rainfall a total of 70,000 horse-power can easily be obtained from the lake.

Anthrax.—In 1913 the Home Office appointed a Committee to inquire into the dangers from infection by anthrax in the manipulation of wool, goat hair, and camel hair. The Committee, of which Sir William Middlebrook, M.P., was chairman, presented their report—a very exhaustive one—on August 22nd last, and it has now been issued in the form of a Parliamentary Paper [Cd. 9171]. As an indication of the laborious character of the inquiry, it may be mentioned that the Committee met on 116 days, visited thirteen representative works, and examined forty-nine witnesses. The conclusion arrived at was that not only are the existing precautions inadequate, but that the danger is one which cannot be dealt with advantageously by regulations, and, given a satisfactory alternative, ought not to be dealt with in factories. Disinfection, the Committee consider, should be permitted only in central stations, preferably ports through which wool is exported to this country. For East Indian wool and goat hair they suggest Bombay and Karachi, for Persian wool Basra, and for Egyptian, Cairo. "The scheme of disinfection should be fitted into the existing trade organisations with as little disturbance as possible, and with sympathetic regard for existing institutions and customs." It is proposed that an organisation designated the "Disinfection Authority" should be constituted by Government and given the necessary powers to prevent the admission of dangerous materials into the country without disinfection. The scheme involves considerable expenditure. Having regard to the objects in view, the Committee recommend that the capital cost should be provided in the first instance by the British Government, the money to be repaid by means of a sinking fund, "provision for which should be made by a charge imposed on wool disinfected."

Engineering and Technical Optics.

NORTHAMPTON POLYTECHNIC INSTITUTE.

ST. JOHN STREET, LONDON, E.C.

ENGINEERING DAY COLLEGE.

Full Day Courses in the Theory and Practice of Civil, Mechanical and Electrical Engineering commenced on MONDAY, 29th SEPTEMBER, 1918. The Courses in Civil and Mechanical Engineering include specialization in Automobile and Aeronautical Engineering, and those in Electrical Engineering include specialization in Radio-Telegraphy.

Entrance Examinations are held annually in September, and Supplementary Examinations at other times. These Courses include periods spent in commercial workshops, and extend over four years. They also prepare for the Degree of B.Sc. in Engineering at the University of London. Fees, £15 or £11 per annum.

Three Entrance Scholarships of the value of £52 each will be offered for competition at the above entrance examination.

TECHNICAL OPTICS.

Day and Evening Courses in this important department of Applied Science given in specially equipped laboratories and lecture rooms.

EVENING TECHNICAL COURSES

in all branches of ELECTRICAL and MECHANICAL ENGINEERING commenced on MONDAY, SEPTEMBER 23rd, 1918. The Laboratories are well equipped for both alternate (single and polyphase) and continuous current work and for all kinds of electrical testing.

Full particulars as to fees, dates, &c., and all information respecting the work of the Polytechnic, can be obtained at the Polytechnic, or on application to

R. MULLINEUX WALMSLEY, D.Sc., *Principal.*

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

COUNCIL.

At a meeting of the Council held on Monday, the 11th inst., the following resolution was passed:—

"That this Council, happening to meet on November 11th, 1918, the day on which, at five o'clock in the morning, an armistice was signed between the Associated Powers and Germany, hereby places on record its deep gratitude to the Naval, Military, and Air Forces of the British Empire for the honourable and heroic part which they have played in bringing hostilities to this happy close."

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One Hundred and Sixty-Fifth Session will be held at 4.30 p.m. on Wednesday, November 20th, when an address will be delivered by ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council. The subject of the address will be "Science and the Future."

The following arrangements have been made for the meetings before Christmas:—

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

NOVEMBER 27.—LORD D'ABERNON, G.C.M.G., Chairman, Central Control Board (Liquor Traffic), "Drink Control in Various Countries." SIR THOMAS BARLOW, Bt., K.C.V.O., M.D., LL.D., F.R.C.P., F.R.S., Past President, Royal College of Physicians, will preside.

DECEMBER 4.—BENJAMIN SEEBOHM ROWNTREE, "Housing after the War." LORD HENRY CAVENDISH BENTINCK, M.P., will preside.

DECEMBER 11.—MAJOR-GEN. SIR FREDERICK SMITH, K.C.M.G., C.B., F.R.C.V.S., "The Work of the British Army Veterinary Corps at the Fronts." The DUKE OF PORTLAND, K.G., G.C.V.O., will preside. (The paper will be illustrated by the cinematograph.)

COLONIAL SECTION.

Thursday afternoon, at 4.30 p.m.:—

NOVEMBER 21.—SIR EVERARD IM THURN, K.C.M.G., C.B., LL.D., "The Present State of the Pacific Islands." SIR CHARLES LUCAS, K.C.B., K.C.M.G., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

NOVEMBER 28.—BHUPENDRANATH BASU, Member of the Council of India, "Some Aspects of Hindu Life." The Most Hon. the MARQUIS OF CREWE, K.G., will preside.

Papers to be read after Christmas:—

SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S. (Subject to be announced later.)

SIR HERBERT JACKSON, K.B.E., F.R.S., F.I.C., F.C.S., "Trueman Wood" Lecture. (Subject to be announced later.)

FREDERICK WILLIAM KEEBLE, C.B.E., M.A., Sc.D., F.R.S. (Director of Horticulture, Food Production Department), "Food Production by Intensive Cultivation."

B. D. PORRITT, M.Sc., Chief Chemist, North British Rubber Company, "The Rubber Industry—Past and Present."

A. F. KENDRICK, Department of Textiles, Victoria and Albert Museum, "English Carpets."

H. KELWAY-BAMBER, M.V.O., "Railway Transport in the United Kingdom."

LIEUT.-COLONEL H. G. LYONS, D.Sc., F.R.S., "Meteorology during and after the War."

W. L. HICHENS (Messrs. Cammel Laird & Co.), "The Wage Problem in Industry."

SIR FRANCIS TAYLOR PIGGOTT, M.A., LL.M., "The Principles of Design in Japanese Art."

J. W. NORMAN WILLIAMS, "The Hawaiian Islands and their Industries."

J. J. CROWLEY, D.Sc., "The Use of Electricity in Agriculture in Germany."

Sir Frank Heath, K.C.B., Secretary, Department of Scientific and Industrial Research, "The Government and the Organisation of Scientific Research."

Walter Leonard Lorkin, A.M.I.E.E., "Electric Welding and its Applications."

Professor John Cunningham McLennan, Ph.D., F.R.S., "Water Powers and Scientific Development in Canada."

Sandford J. Kilby, "Indian Salt Manufacture."

H. Kelway-Bamber, M.V.O., "Coal and Mineral Traffic on the Indian Railways."

Professor H. E. Armstrong, LL.D., D.Sc., F.R.S., "Soil Exhaustion in India and its Influence on the Value of Crops."

Lord Montagu of Beaulieu, C.S.I., V.D. (Subject to be announced later.)

Further arrangements were announced last week.

EXAMINATIONS, 1918.

The diagram on page 795 shows the progress of the Society's examinations from the beginning of the present century. It will be seen from this that the number of candidates rose steadily from about 9,000 in 1900 to 29,000 in 1914. The effect of the war is very clearly shown in the sudden drop to 23,400 in 1915, and the still further fall to 19,300 in 1916. At this point the fall was arrested, and for a year the number remained almost stationary, the total in 1917 being 19,400. This is accounted for to a large extent by the fact that, although a great many who would otherwise have entered for the examinations had joined the Services, there was a great increase in the number of women candidates. This year the proportion of women is still higher, with the satisfactory result that the figures for 1918 show an increase of 3,400, as compared with those of last year. It may therefore be anticipated with considerable confidence that the examinations have already suffered the worst that the war could inflict on them. Next year, indeed, we may look for a further substantial rise. At the request of the War Office arrangements are being made for holding in February special examinations for troops on active service. Centres will probably be formed in France, Italy, Egypt, and at home. It is not yet possible to make any sort of estimate of the numbers likely to enter for these examinations; but, according to reports, a large number of the troops are availing themselves of the educational opportunities which the authorities of the Government are now providing for them.

As has been the case since 1914, the examinations this year were held at two periods, March and May–June. In March the number of candidates was 8,116, and in May–June 14,698. The numbers of papers worked were divided between the two examinations as follows:—

	March.	May.	Total.
Advanced Stage	563	2,447	3,010
Intermediate Stage	2,842	7,159	10,001
Elementary Stage	6,855	9,013	15,868
	10,260	18,619	28,879

The papers worked at the various Internment Camps abroad are included in the above table, but not in Table A on page 796.

In addition to the 22,814 examined in the written examinations, 256 candidates presented themselves for the *vivâ voce* examinations in Modern Languages. The total number of candidates examined in all subjects by the Royal Society of Arts in 1918 was, therefore, 23,070.

No changes of importance were made in the examinations programme this year. The subjects were: Arithmetic, English, Book-keeping, Shorthand, Précis-writing, Typewriting, Economic Geography, Economic History, Economic Theory, Commercial Law, Company Law, Accounting, Banking, Theory and Practice of Commerce, Commercial Correspondence and Business Knowledge, English for Foreigners, French, German, Italian, Spanish, Russian, Dutch, Rudiments of Music, and Harmony.

The total number of papers worked in Arithmetic was 2,743. The largest number of entries in this subject was in 1914, when the figure was 3,225. In 1915 this fell to 2,806, and in 1916 there was a further fall to 2,226. In 1917 there was a slight recovery to 2,349, and this has been continued in the present year by a rise to 2,743. Of these, 101 candidates entered for the Stage III. examination, of whom 4 obtained first-class certificates, 31 second-class certificates, and 66 failed. These results are exceedingly poor, and it is evident, as the examiner reported, that the great majority of the candidates did not possess the skill and knowledge necessary for this standard. The

results in the Stage II. examination were appreciably better, though the examiner has to complain of the lack of intelligence as well as of arithmetical knowledge in many candidates who misunderstood the meanings of the questions. The report on the work done at the Stage I. examination is very satisfactory.

There was a remarkable increase in the number of entries in English, the total 1,074 being considerably higher than in any previous year. Of these, 45 were in Stage III., 248 in Stage II., and 781 in Stage I. There seems to have been a general fall in the level of attainment in the Advanced Stage, though the work of the best candidates remains as good as ever.

The examination in English for Foreigners was instituted in 1916, on the suggestion of the Bradford educational authority that such an examination would be useful to a number of Belgian refugees in this country. In that year there were 547 entries. This figure dropped to 260 in 1916 and to 195 this year. The examination was, of course, only designed to meet a war-time need, and it is to be hoped that before the examinations are held again most of the refugees will have been repatriated.

Précis-writing no longer has the vogue that it once enjoyed. As a subject of examination it has been abandoned, to a very large extent, by the Civil Service Commissioners, who as a rule content themselves with setting a piece of narrative instead of a set of correspondence, with numerous letters to be indexed and docketed. This general tendency is reflected in the figures of the Society's examinations in this subject, which fell from 362 in 1911 to 74 in 1916. Last year, however, there was a slight rise to 85, and another to 95 in 1918.

The total number of entries in Commercial Correspondence and Business Knowledge was 2,430, showing a very considerable increase over last year's figure, 1,973. Unfortunately, with the increase of quantity there does not appear to be any corresponding improvement in quality. Of the 56 candidates who entered in Stage III. none obtained a first-class certificate, only 19 obtained second-class certificates, and 37 failed. In Stage II., again, of 420 candidates, only 9 obtained first-class certificates, 177 obtained second-class certificates, and 234 failed. The results are very unsatisfactory, and no doubt show, as the examiner suggests, that the instruction has proceeded on too narrow a basis.

The number of papers worked at the examinations in book-keeping was 8,023, of which 862 were in Stage III., 2,549 in Stage II., and 4,612 in Stage I. Book-keeping has always been the most popular subject of the examinations, the number of entries in 1914 being as high as 11,883. This dropped in 1916 to 6,687, but it now looks as if it were on the way to recover its pre-war dimensions. The examiner's report shows that this year the work on the whole is fair. He complains that many candidates were weak in dealing with income tax—which is, perhaps, more a matter for sympathy than surprise.

In Shorthand, which is, as usual, the second favourite subject, the figures for 1918 show a substantial increase over those for 1917 in each stage, the totals for the two years being 7,527 and 5,982 respectively. The examiner has gleaned his usual supply of quaint misrenderings, among which the most remarkable were "period of sinking" for "uprooted cinchona," "party government" for "uprooted coffee," "shop supplies" for "shipping space," "the least possible delay" for "the latest possible detail," and "for their manufacture" for "over from America." To the layman these blunders must seem simply fatuous and inexplicable; but anyone with a knowledge of shorthand outlines will see how they have arisen.

The number of entries in Typewriting, 2,589, shows an increase of 141 over the total of last year, and the results are very satisfactory. In Stage III., out of 117 candidates, 37 obtained first-class certificates, 62 obtained second-class certificates, and only 18 failed. In Stage II., out of 814 candidates, 179 obtained first-class certificates, 500 obtained second-class certificates, and 135 failed; while in Stage I. 1,256 passed out of 1,658. The examiner reports that the work on the whole was excellent, and decidedly in advance of the average of former years.

In Economic Geography there were 206 candidates in all, of whom 14 entered for the Stage III. examination, 51 for Stage II., and 141 for Stage I. It is satisfactory to note that the examiner reports "a very remarkable improvement" in the Stage III. and Stage II. papers. Although this total (206) is more than double that of last year (98), one would like to see a great increase in the numbers of entries, for there can be no doubt that in a community such as the British Empire, with its enormous geographical distribution and commercial interests, this subject is of vast importance, and ought to attract considerable numbers of serious

students. But doubtless in this, as in many other subjects, a great number of those who would normally have been candidates are engaged on active service.

In Economic History there were only 13 candidates for the Stage III. examination, and 16 for Stage II. The general level of the work seems to have been fairly satisfactory; but here, again, one would like to see a substantial increase in the number of entries.

It is somewhat remarkable that of the 59 candidates who entered for the examination in Economic Theory, 33 took the Stage III. examination, and 26 the Stage II. One hardly expects to find more entries for the Advanced than for the Intermediate Stage. The examiner's report on the Stage III. examination throws some light on this point: "too many [of the papers] were superficial and inaccurate, and the writers should not have attempted this stage of the examination."

The candidates in Commercial Law numbered 77, and those in Company Law were 54, as compared with the respective totals 65 and 41 in 1917. The examiner reports very favourably on the work done in both these subjects, and certainly the proportion of first classes is very large and that of failures very small.

There were 142 candidates in Accounting, as compared with 122 last year. The general average of merit appears to have been good. The examiner in Banking reports to the same effect on the work of his candidates, of whom there were 37, as compared with 29 in 1917.

The total number of candidates entering for Theory and Practice of Commerce was 210, of whom 55 took the Stage III. examination, and 155 Stage II. This examination was held for the first time in 1914, when there were 154 entries. Since then the figures have been 233 in 1915, 226 in 1916. and 180 in 1917. The examiner reports that numbers of the papers worked this year were very poor. The explanation is probably to be found in his surmise that many candidates take this subject at an age when they are quite unable to appreciate it properly.

The number of entries in French was 2,248, of which 507 were in Stage III., 832 in Stage II., and 909 in Stage III. The total entries in this subject during the last four years were: 2,954 in 1914, 2,784 in 1915, 2,285 in 1916, and 2,041 in 1917. In 1914 there were 793 entries in Stage III., so that the number for this year is still a good deal lower than the pre-war figure; but after all this is hardly matter for wonder, as so many of those who would have been advanced students are engaged on military or naval work. It is perhaps permissible to hope that after the war there will be a considerable increase of entries in the Advanced Stage, in view of the opportunities for studying French which have been afforded to large numbers of our soldiers. On the quality of the work done in Stages II. and III. the examiner presents a very favourable report.

One of the effects of the war is strikingly evident in the figures of the entries in German, the hatred of the enemy having evidently extended to his language. In 1914 the total in all stages was 826. In 1915 this fell to 462, in 1916 to 270, in 1917 to 215, and this year to 181. Of these, 35 entered in Stage III., 49 in Stage II., and 97 in Stage I. The work of the candidates appears to have been satisfactory, especially in the Advanced Stage.

The entries in Italian (80 in all stages) are satisfactory in so far as they exceed the pre-war figure of 76 for 1914; and there is a substantial rise as compared with the 53 entries of last year. Speaking generally, the work of the candidates appears to be fairly good.

In Spanish the entries were 289. The figure in 1914 was 355, but this had fallen in 1916 to 149. There seems to be considerable room for improvement in the work, especially in Stage III., where out of 42 candidates only 2 secured first-class certificates.

The figures in Russian are not uninteresting. Up to 1914, when there were 17 entries in all stages, the numbers were very small. In 1915 no examination in this subject was held. The events of that year, however, roused great interest in Russia, with the result that in 1916 there were 127 entries, which number increased to 266 the following year. It will probably be some time before we reach this figure again, for in 1918 the number had fallen to 157. This year's work in Stages II. and III. appears to show considerable improvement on that of preceding examinations.

Dutch has always attracted so few candidates that only on one or two occasions has it been found possible to hold an examination in this subject. This year only one candidate in this country presented himself. There were, however, a number of interned men in Holland who were anxious to be examined. As no fees are charged by the Society to prisoners of war and interned men it was at first doubtful if the examination could be held; but two donations of £20 each from the Directors of the Standard

Bank of South Africa and of the National Bank of South Africa removed the financial difficulty.

In Rudiments of Music there were 71 entries, as compared with 78 last year; and in Harmony 49, as compared with 50.

Oral examinations were held in French, German, Italian, Spanish, Russian, and English for Foreigners. The total number of candidates was 256 (as compared with 261 last year), of whom all (except 19 who were examined in Manchester) presented themselves at various centres in London. The numbers in the different languages were: French 176, German 17, Italian 16, Spanish 11, Russian 6, English for Foreigners 30. The details of the results of the oral examinations are given in Table B (page 797).

It is much to be regretted that the number of candidates entering for these oral examinations is so small. They have never been as large as they ought to be, in view of the importance of a colloquial knowledge of the subject in the case of a modern language. The highest number yet reached was 688 in 1913, since when the figures have steadily declined. It is, perhaps, permissible to hope that, now that so many possible candidates have had opportunities of studying foreign languages abroad, there may be an improvement in the numbers; and possibly, also, the newly instituted general certificate in modern language may induce a few candidates to enter.

The Court of the Clothworkers' Company have again renewed their grant of £40, to be expended in providing medals in all the subjects of examination where the work of candidates attains a sufficiently high standard. There is no doubt that these medals are highly valued by those who win them, and they have done much to maintain or raise the level of excellence in the papers worked. This year the Society has awarded 20 Silver Medals in the Advanced Stage, and 32 Bronze Medals in the Intermediate.

The arrangements made in 1916 and 1917 to enable prisoners of war and men interned abroad to enter for the Society's examinations were again repeated this year. The May examinations only were taken at Ruhleben, where 119 papers were worked by 58 candidates. Of these, 89 papers were in Stage III., of which 10 failed; 21 entered and passed in Stage II., while in Stage I. 9 papers were worked, of which 7 passed. The subjects taken up included Accounting, Book-keeping, French, German, Italian, Russian, and Spanish. The examiners in these languages report that the work of the candidates attained a high level of excellence. In German, *e.g.*, 26 candidates entered for the Stage III. examination, and of these 23 received first-class certificates, and the remaining 3 second-class certificates—a truly remarkable result.

Candidates from the British Naval Brigade interned at Groningen entered for both examinations. 91 papers in all were worked—22 for the Advanced Stage (12 passes and 10 failures), 43 for the Intermediate Stage (33 passes and 10 failures), and 26 for the Elementary (17 passes and 9 failures). The subjects were Arithmetic, Accounting, Book-keeping, French, German, Dutch, and Spanish.

At Chateau d'Oex 67 papers were worked in a variety of subjects at the two examinations. Of these 7 were in Stage III. (5 passes and 2 failures), 27 in Stage II. (24 passes and 3 failures), and 33 in Stage I. (26 passes and 7 failures).

At Mürren there were 16 candidates for the May examinations; 1 entered and passed in Stage III., 11 entered for Stage II. (of whom only one failed), and 4 took Stage I., none of whom passed.

The Examination Syllabus for 1919 has been issued. In it will be found the fullest possible information about the examinations, a syllabus of each stage of each subject, and a list of centres. The papers set in March and May, 1918,* have been reprinted in six pamphlets. Each pamphlet contains, in addition to the papers of each stage, the syllabuses of the subjects in the pamphlet and the examiners' reports on the papers worked in 1918. The attention of both teachers and students may be drawn once more not only to the syllabuses but also to the remarks of the various examiners on the results of last year. It will be found that these contain many valuable and helpful suggestions, and the work of the candidates year after year shows that far too little attention is paid to them. Teachers especially are earnestly recommended to study these reports, as they ought to be guided by them in the instruction they give to their pupils.

The regulations for the Examinations in the Theory of Music, and those for the Viva Voce Examinations in Modern Languages, are also given at full length in the syllabus.

* The price of the Syllabus for 1919 is 3*d*. post free. Copies can be obtained on application to the Examinations Officer, Royal Society of Arts, Adelphi, London, W.C. (2) The price of the pamphlets containing the 1918 papers is 3*d*. each, post free. Particulars of these may be obtained as above.

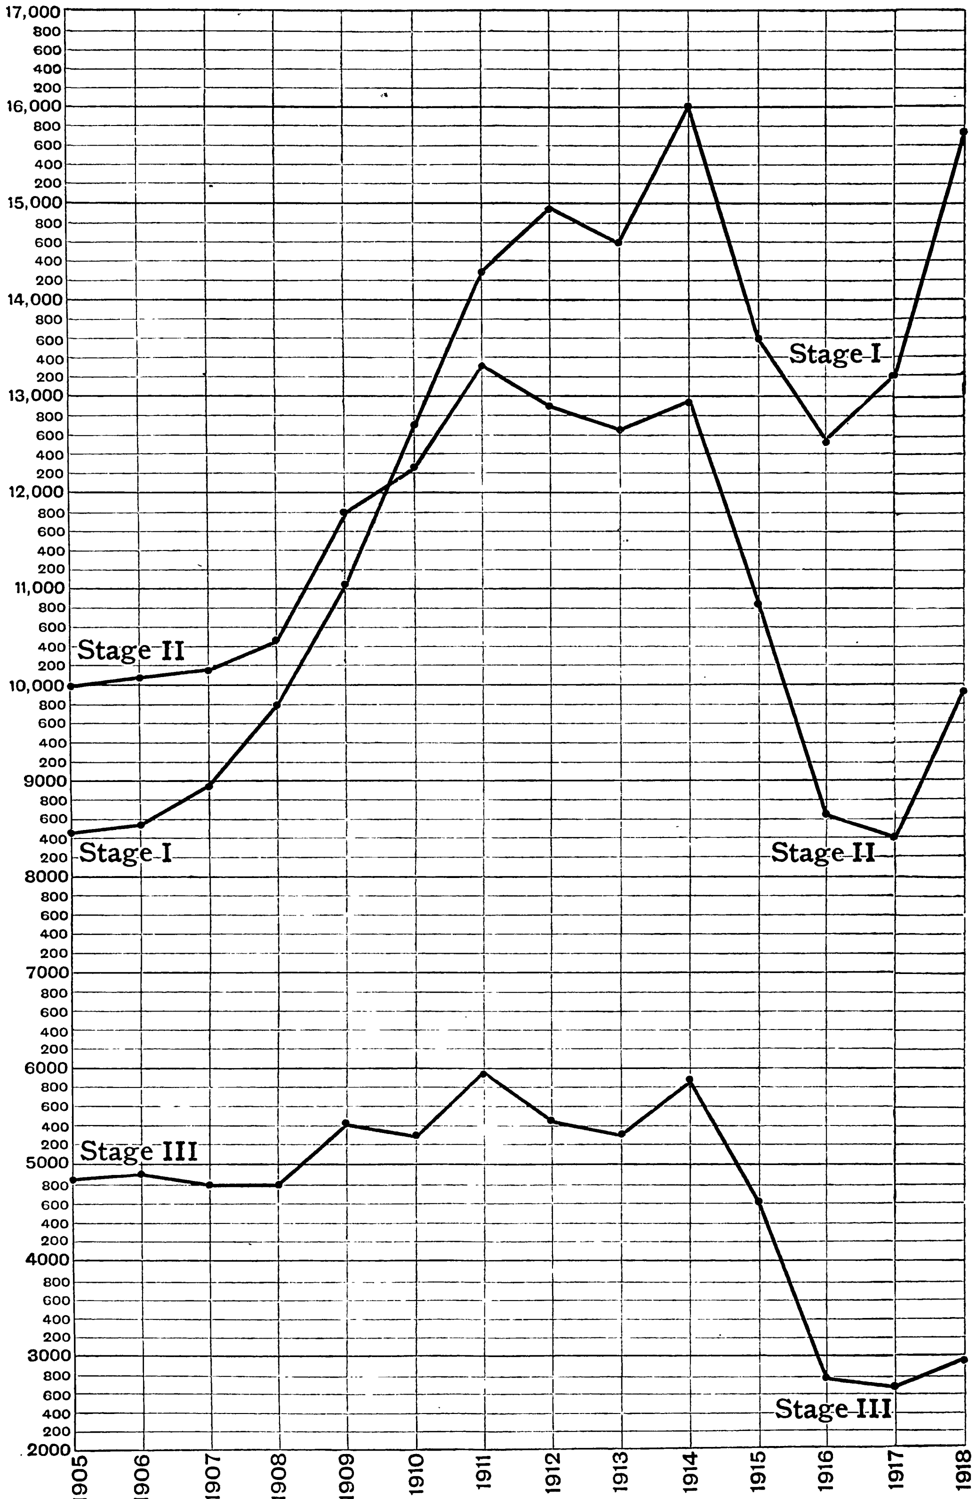

Diagram Showing the Numbers of Papers worked in the Three Stages, 1905-1918.—
I. Elementary; II. Intermediate; III. Advanced.

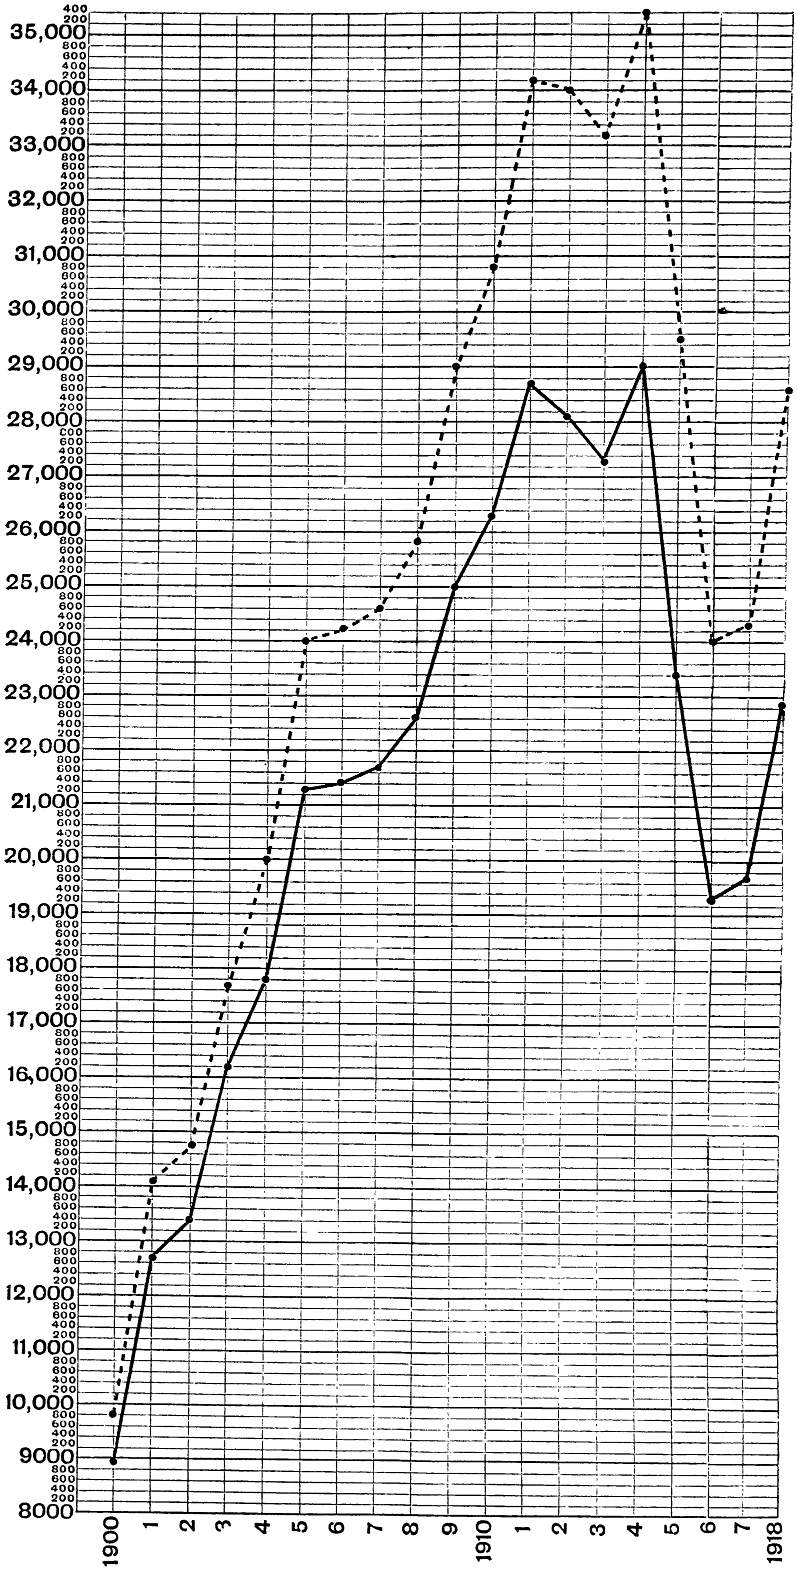

DIAGRAM SHOWING PROGRESS OF EXAMINATIONS, 1900-1918.

The continuous line shows the number of candidates, the dotted line the number of papers worked.

VEGETABLE WAX INDUSTRY OF JAPAN.

A Japanese industry which has made remarkable progress in recent years is that concerned with the extraction of vegetable wax, which is coming into greater demand on foreign markets. The output has been gradually increasing and now stands in the neighbourhood of 1,700,000 yen, or about £174,000 per annum. The work of extraction is being organised on a larger scale.

According to a report published by the United States Department of Commerce, the principal regions of production are in the island of Kiushiu, especially around the city of Fukuoka, which accounts for nearly half of the total output. The product is used abroad principally in the manufacture of polishes, pomade and soaps, and in dressing leather.

Most of this vegetable wax is derived from the fruit kernels of a tree peculiar to Japan, which begins to fruit at about fifteen years, and sometimes bears heavily when it is over a hundred years old. It reaches a height of 20 to 25 ft., and produces from 30 to 150 lb. of nuts annually. The best wax is made from nuts that have been kept over the winter, and, generally speaking, the quality of the product improves with the age of the nut. The wax is extracted by crushing and steaming the nuts, and then subjecting the mass to pressure. A second wax is secured by re-pressing. One workman can handle about 150 lb. of raw mass in a day, and this produces about 16 lb. of wax.

The crude wax, which solidifies at 50 degrees, is cast into round moulds of a little more than a pound each. It is next refined, the process used being a traditional one and peculiar to Japan. It is mixed with wood or charcoal, ash and water, thoroughly boiled, and dropped into cold water, so as to form what are called wax flowers. These are taken out and exposed to the sun for about twenty days, when the process of boiling, making the flowers, and sunning is repeated. The wax is then

boiled a third time, and the best quality taken off the top while it is in a molten condition. Recently improved methods have begun to come into use, and the crude wax is treated with an alkaline solution.

The most important foreign consumers of this product are the United States, Great Britain, France, and Hong-Kong, followed by various other countries of the Orient and Europe.

OBITUARY.

JOSEPH BLAMIRES.—Mr. Joseph Blamires died at Harrogate on November 5th, at the age of fifty-seven. He was head of the firm of Messrs. T. & H. Blamires, Ltd., woollen manufacturers, of Huddersfield.

In addition to his business activities, Mr. Blamires took a keen interest in municipal government, and was Mayor of Huddersfield for four years. He also worked to secure the extension of the Technical College, and was one of the principal workers in the movement that led to the establishment of British Dyes, Ltd. He was a director of the West Yorkshire Bank, and of the Huddersfield Building Society.

He was elected a Member of the Royal Society of Arts in 1910.

GEORGE CHELLEW.—Mr. George Chellew, who joined the Society in 1917, died on October 19th, at the age of twenty-five, from influenza and pneumonia. He was educated at King's College, London, and became a Science Master at a secondary school. He served in the Royal Fusiliers.

GENERAL NOTES.

THE "ENGLISHWOMAN" EXHIBITION.—The *Englishwoman* Exhibition of Arts and Handicrafts was opened at the Central Hall, Westminster, on the 13th inst., and will remain open until the 23rd. This is the eighth year that the exhibition has been held. The exhibits include weaving, pottery, toys, model buildings, etc. A special feature is the work of the wounded and permanently disabled soldiers and sailors who are trained at St. Dunstan's and Kitchener House.

SUBSIDIES.—Some months ago it was officially stated in the House of Commons that subsidies are granted to manufacturers of iron and steel to compensate for the increased cost of production. Replying to a question on the subject on November 7th, Mr. Kellaway (Ministry of Munitions) said that it would be impossible, within the limits of a Parliamentary answer, to give the scales of the subsidies, but it was estimated in July last that grants amounting to £17,000,000 had been approved. Recent increases had had to be given, owing to the further rise in the cost of coal and rates of wages. The Government is practically the only buyer, being the purchaser of 98 per cent. of the output. He added: "A Committee is now sitting with a view to seeing how soon the arrangement can come to an end in the event of the cessation of hostilities."

OIL FROM ALUM SCHIST.—A factory for extracting oil from alum schist has been started in Sweden. Large quantities of this schist, yielding benzine and crude oils, are found in the Lamma Nerika district. The crude oils, according to *Teknisk Ukeblad* of August 30th, can be used for oil-engines or converted into paraffin and lubricating oils. The factory is capable of treating 30,000 tons of schist per annum, giving 1,200 tons of oil. The supply of schist in Sweden is practically inexhaustible, and other factories will be erected shortly.

FISHERIES RECONSTRUCTION IN GERMANY.—A great deal is being done in Germany in connection with technical and scientific research in fisheries, and some account of it is given in the *Fish Trades Gazette* of October 26th. At Munich a great research institute has been founded for the study of the chemistry of food. It is intended to serve the interests of the whole Empire, and will be richly endowed. A sum of £150,000 to £200,000 has been set aside for building and equipment, and the annual revenue will be from £5,000 to £10,000. It is intended to make researches on the chemical composition and digestibility of all kinds of fish, fresh and preserved; on the effect of cold and other agents on its preservation and transport; on various methods of cooking fish; and on the so-called "fish-poison," or poisoning by bad fish.

SUGAR IN MAURITIUS.—This year's sugar crop in Mauritius promises to be one of the largest ever reaped. The Sugar Commission, however, has stated that it may not be possible to ship any considerable portion it to this country, and the Colonial Government will buy up the greater part of it. The Governor, in his address to the Council of Government last May, drew attention to the fact that no less than 43 per cent of the 1917 crop was produced by independent Indian farmers, a figure which, he observed, was the best reply to the arguments of those parties in India who are trying to prevent the emigration of Indian agriculturists to the colony.

Offer of a set of "Journals."—A set of unbound *Journals*, in good condition, extending from 1909 to 1918, has been placed at the disposal of the Secretary of the Royal Society of Arts for presentation to a public library or institution which will undertake to bind and preserve them. Applications should be addressed to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. (2)

CONTRIBUTIONS TO THE READING-ROOM.
